MR. H. MANSFIELD ROBINSON, LL.D., clerk and solicitor to the Shoreditch Vestry, has pointed out to the Lord Mayor that the provision in the new Public Health (London) Act, 1891, which requires sanitary inspectors to possess certificates of competency would do more harm than good unless such certificates were granted only after a proper practical test.

THE Italian Government has just issued an "ordinanza" recalling into force that of November, 1892, which establishes medical examination of all ships hailing from French Mediterranean seaports, with power to relegate the same to the sanitary stations in cases of suspected illness on board. The "ordinanza" also interdicts the introduction of soiled goods from France into Italy, by land or sea, until these have been disinfected.

THE second Hunterian Society lecture of the session will be delivered by Mr Walter Rivington, B.A., M.S. Lond., consulting surgeon to the London Hospital, on Wednesday next, the 22nd inst., at the London Institution, Finsbury Circus. The lecture is open to all members of the medical profession. Its subject will be "Certain Branches of Operative Surgery."

THE annual public meeting of the University College Chemical and Physical Society will be held at the College on Friday, Feb. 24th, when an address will be given by Professor Watson Smith, F.I.C., F.C.S., entitled "Diseases incident to Workpeople in Chemical and other Industries." The chair will be taken by Dr E. T. Roberts at 8 P.M. Specimens of apparatus will be on view.

A CONFERENCE of representatives of the Port Sanitary Authorities of England and Wales, having for its object the consideration of the necessary measures for the prevention of the introduction of cholera into this country, will be held, in the Council Chamber of the Guildhall, to-day (Friday) at 2 P.M., under the presidency of the Lord Mayor.

THE members of the Anatomical Society of Great Britain and Ireland will hold their general meeting on Feb. 27th, at 4.30 P.M., at Charing Cross Hospital Medical School. After the election of new members a number of interesting specimens of abnormalities will be exhibited and three papers will be read.

THE 120th anniversary dinner of the Medical Society of London will take place at the Whitehall Rooms, Hôtel Métropole, on Wednesday, March 8th, at seven o'clock precisely, Jonathan Hutchinson, Esq., F.R.C.S., F.R.S., President, in the chair.

HER MAJESTY has selected Dr William Job Collins to be a Fellow of the University of London in the place of the late Lord Sherbrooke. Dr Collins's name was placed first on the selected list by the recent vote of convocation.

WE understand that Professor Charteris of Glasgow University has been requested to prepare and read a paper on Sea sickness before the Congress of Médico Climatologists at the Chicago Exhibition, and that he has consented to do so.

DR. CHARLES CHAUVET, formerly *chef de clinique* in the Lyons Faculty of Medicine, has been sent by the French Government to Russia for the purpose of studying the frequency, the causes, and the treatment of neurasthenia.

THE Milroy Lectures will be delivered by Dr A. Whitelegge in the theatre of the Laboratories, Examination Hall, Victoria Embankment, on Tuesday and Thursday, Feb. 21st and 23rd, at 5 P.M.

ON Friday, Feb. 17th, a dinner was given by the Port Sanitary Committee of the City of London at the Albion Tavern, Aldersgate street, London. Mr David Burnett occupied the chair, and amongst those present were the Right Hon. the Lord Mayor and the Sheriffs and representatives of the Port Sanitary Authorities of England and Wales.

entertain or consider any proposals tending to connect the State with hospital management, which appeared to be as much a *dele noire* to them as it seems also to be to the uncompromising advocates of private charity and thrift.

The limits of the voluntary principle have evidently been reached and passed in London. One of the most learned and benevolent workers and writers on the management of the poor said, in dwelling on this subject some fifty years ago, that when the subject of private charity is thus narrowed, if we trust to experience and not to speculation as our only safe guide, there is clear and overwhelming evidence of the inadequacy and insufficiency of voluntary charity in advanced stages of society, to supply what is needed for the wants of the poor in their own interests and in those of society itself. This is, indeed, the guiding principle of the Poor laws themselves when administered with the care, judgment and humanity required to mitigate those elements of harshness which are to a great extent inseparable from them.

Upon this subject, after careful study and considerable personal experience, I entertained and published some ten years since, in THE LANCET and elsewhere, when advocating an official inquiry into the subject, views and suggestions which are as applicable now as they were then and long before. We have recently had our distinguished committee of inquiry, not exactly in the form best adapted to settle the question, yet a notable and valuable landmark for future guidance. This inquiry has thrown some most useful side-lights, but afforded no fresh information on the subject, and the question appears to be little nearer to solution than when dealt with by Sir John Simon in 1863 and by myself in 1883. Another decennium has passed and a century has elapsed since the promulgation of the masterly report of Tenon, yet the whole question is again under review.

But times and thoughts and manners and customs have since undergone complete and almost revolutionary changes in their adaptation to the progress and wants of the present. In the high pressure life of the Victorian era, in most social and almost all national and international relations, old landmarks have been removed, and the accepted facts of yesterday have become the rejected fictions of to-day. The rapid advances of science in its applications to the purposes of life in association, have added much to the comfort and happiness of mankind, and in no branch of sociology has this been more manifest than in the progress of medicine in the relief of sickness and the prolongation of life. To it we owe the priceless blessings of extinction of pain in disease and the robbing of many sources of destructive diseases of their powers of evil.

Why, then should not our hospitals be brought into harmony with this progress, and accept instead of reject changes which have become imperative? It is true that some old practices and customs die hard, more especially when those who have a personal interest in their continuance resent any interference with them. Yet, it is impossible in the long run to resist the advancing tide of civilisation, and it is wiser to bend than to end such matters. For example, there are few problems connected with the phenomenal growth of London that are more complex in character more encumbered by conditions of life of which little that is certain is known, and in consequence more difficult of solution than that of the relief of the sick poor in an aggregation of human beings on a restricted area, some 30 000 or more to the square mile such as the world has never before seen. They comprise every caste, class and almost race and condition of life from the highest down to the most squalid objects of misery, destitution and suffering in existence, most of which conditions are factors of more or less significance which need consideration in dealing with all the greater problems of sociology connected with the management of the poor.

I would rather reproduce what I wrote on the subject some years ago than consider it with the light and experience that have since been brought to bear upon it, for obvious reasons. I then said that from a careful review of the whole question taking into account the vast proportions of the poor of London [and of those immediately above them, the artisan and working classes generally] the resources of the general hospitals voluntary and endowed, are becoming dangerously strained, that from their quasi-alms character and consequent conflicting regulations and interests a large number of the really poor for whose relief they are intended are excluded from their benefits whilst many who can afford to pay for medical care and treatment receive them gratuitously, a demoralising proceeding, tending to prevent the exercise of thrift and

destroying the principle of self restraint and self denial in even a more objectionable manner than the grave abuses of the out-door medical relief intended for the permanently destitute.

General and indeed all other hospitals are public institutions of the first necessity, and no personal or proprietary rights in relation to them should be permitted to interfere with their regulation in the interests of the public. This regulation can be carried out so as in no way to interfere with the maintenance of such control and management by the subscribers and supporters, as will not be inconsistent with that object. A system can surely be devised to harmonise public aid with the action of the voluntary institutions so as to secure to the latter all such rights and privileges as can be justly allowed in the terms of their charters and the conditions of their subscriptions and bequests, but always without detriment to their primary purpose—the relief of the sickness of the poor compelled to resort to public institutions in their hour of need. Charity should not, I think, be a purchasable commodity, and I concur entirely with those who are of opinion that it is not money so much as organisation that is most needed. Charity would then occupy its proper place in all schemes of benevolence, and not be allowed to assume a predominating voice and influence in the management of such composite institutions as hospitals. In my next communication I shall examine various details of the question which are contained in the report of the Select Committee of the House of Lords.

Durham Villas Kensington W

CHOLERA.

CURRENT NOTES, COMMENTS AND CRITICISM.

THE sharp outbreak of cholera at Marseilles, to which we called attention last week, like other outbreaks of a similar nature elsewhere, attained its maximum development in the course of a few days and then began to decline. On the 11th inst. there were only 6 deaths from choleraic disease, and on the following day there were 8 deaths registered from the same cause and a few fresh cases were also reported. We have no official notification of the exact nature and extent of the disease that has prevailed, nor have any assigned causes of its origin been definitely stated. It is alleged, however, that the comma bacillus had been found in one case, but not in all the cases that had been bacteriologically examined. The sanitary state of Marseilles is now stated to be satisfactory. Since the 13th inst. no deaths or fresh cases of choleraic disease have occurred.

The reports from the Nettleben Asylum are satisfactory, the outbreak at that institution, although of a very severe and fatal character, having run its course within a comparatively limited time.

It is important to preserve a precise record of the facts connected with these circumscribed outbreaks of this disease in order to see whether some law or average cannot be deduced by comparing a number of these occurrences together as to what is the duration of such outbreaks under given circumstances. Cholera, like other diseases, has its own natural history and laws and until a systematic attempt is made to arrange and classify all the facts about it we are not likely to formulate any scientific and useful conclusions. Results that are natural and would in any case have followed in due course are likely to be sometimes erroneously attributed to the action that we have ourselves taken, unless we first of all know what is the natural course of an epidemic disease under given circumstances.

A VISIT TO CALAIS

How Cholera came to Calais.—Forcible Measures.—Draining into Canals.—The Channel Steamers and Cholera.—The Subsoil Water

WHEN describing the improved facilities for travelling on the Continent I gave some account of the drainage of Calais and the progress that had been accomplished of late years, but, though many new sewers have been built, as will be seen

show that bromide of ethyl narcosis can be obtained while the blood pressure remains normal, and that when too much bromide of ethyl is given the cessation of respiration precedes that of the heart, but, at the same time, his experiments prove that large quantities introduced into the blood cause considerable disturbance in the heart's action. This last point is one of great practical importance, and shows that in bromide of ethyl narcosis the same precautions ought to be taken as in the administration of chloroform. Anæsthesia comes on rapidly but goes off very soon after the inhalation is stopped, though where the operation is a long one care must be taken that the patient should inhale a sufficient quantity of the vapour. Although bromide of ethyl cannot in all cases serve as a substitute for chloroform, Dr Ginsburg is convinced by personal experience that it is frequently preferable to the better known anæsthetic.

ON THE ORGANISATION OF MEDICAL RELIEF IN THE METROPOLIS

By F J MOUTAT, LL D, M D EDIN, F R C S ENG

PART II

'Quousque tandem abutere patientia nostra?'

AFTER many years of discussion and consideration, with several unsuccessful efforts on the part of the medical profession to obtain an authoritative investigation of the management and working of the hospitals and cognate subsidiary institutions of the metropolis, the Charity Organisation Society—an irresponsible non medical body—procured the appointment of a Select Committee of the House of Lords to obtain evidence and report upon the matter. The formulation of the resolution, which was moved by Lord Sandhurst and agreed to, did not contain any indication of more than a restricted investigation, in which some of the most important factors involved had no place. The financial and charitable aspects of the many questions which needed investigation were manifestly the main purpose of the inquiry, as might be expected from its motive power. Their lordships, however, fortunately interpreted their functions more largely and liberally, and yet not sufficiently so to prepare a matured case for legislative action, as I shall endeavour to show in my review of their report.

The resolution was as follows: "That a Select Committee be appointed to inquire with regard to all hospitals and provident and other public dispensaries and charitable institutions within the metropolitan area for the care and treatment of the sick poor which possess real property or invested personal property in the nature of endowments of a permanent and temporary nature, and to receive, if the committee think fit, evidence tendered by the authorities of voluntary institutions for like purposes or with their consent, in relation to such institutions and further to inquire and report what amount of accommodation is provided by rate and as to the management thereof, and that the witnesses before the said Committee be examined on oath." Accordingly a strong committee of fifteen members, headed by the Archbishop of Canterbury, was formed, and first met on May 5th, 1890. The committee sat for two years and furnished three reports, as well as an excellent analysis of the evidence taken, together with tabular statements of the system of government of all the general and special hospitals and dispensaries and useful details of such particulars as are necessary for their right understanding. These tables are somewhat difficult of reference, but are of great present and future value in the study and determination of the very important questions to which they refer. I endeavoured, in studying the evidence and report, to compare the latter with that of Messrs Bristow and Holmes in 1863 in their bearings on the questions as a whole, but I found that no comparison was possible, as the two inquiries were conducted on different lines and for a different purpose. The one was by experts who were thoroughly acquainted with the task before them, the other was by noble men eminent in entirely different and more exalted walks of life and of unimpeachable impartiality, but possessed of no technical knowledge and previous training to guide them in expressing an authoritative judgment on the purely medical and scientific aspects of the inquiry committed to

their charge. The absence of such knowledge was evident in much of the evidence taken with a patience and manifest desire to get at the truth which command grateful acknowledgment. But the net result of the proposed solution of the question is to substitute as a ruling power, *caritas for sanctas*, a position which the recent proceedings of the subcommittee appointed to frame a scheme for a Central Board of Hospital Control for London render it probable will not be accepted by the authorities of the institutions to which it was to be applied. It will thus prolong a period of *laissez faire* which has already lasted much too long, and which is calculated to culminate in the undesirable transfer of the whole matter to the State. The interests of the sick poor are far too important to be sacrificed or subordinated to the precariousness of private charity or the continued untrammelled control of bodies which have heretofore successfully resisted all public scrutiny of their proceedings.

The committee in their concluding paragraphs foreshadow this in formulating their suggestions for the creation of a central hospital board for London—

Paragraph 624—In sketching the foregoing outlines of a central body, the committee are desirous of expressing their opinion that some more satisfactory organisation of medical charity is most desirable. It should always be borne in mind that the establishment of Poor law infirmaries and rate-supported asylums under the Metropolitan Poor law Act of 1867 has in great measure altered the relations between the poor and the hospitals, and everything associated with medical charity, and the committee cannot shut their eyes to the possibility, if some such organisation as they have recommended is not adopted, that a time may come when it will be necessary for hospitals to have recourse to Government or municipal subvention.

Paragraph 625—It is shown by the evidence that, apart from the three endowed hospitals, the general hospitals in London are maintained principally by the legacies they receive and by large donations from unexpected quarters. In most cases the subscriptions from annual subscribers do not suffice to pay the wages of the servants and nurses in the service of each hospital, to say nothing of the cost of maintenance and administration. It has been authoritatively stated that from £50 000 to £55 000 per annum are required to render available the 1800 or 2000 vacant beds which are said to exist.

Paragraph 626—One endowed hospital is maintained entirely by its endowments, but the two others are so short of funds that many beds are closed to the sick poor.

How is it possible, in the face of so startling a revelation as this, to maintain the existing system? A speculative and unsound scheme of socialism can command a levy of £100,000 with a demand of £30 000 annually for its maintenance. An endowed hospital, with a diminished endowment of £28 000 a year—which ought, however, by careful and judicious economy and management, to be amply sufficient to fill its beds—can also raise £100,000 which is employed for its current needs, instead of adding to its permanent income, whilst most of the voluntary hospitals are starved. There are other indications of injudicious or extravagant management which appear to me to prove that the time of change of procedure predicted by the Lords' Committee has arrived, and that the setting in order of the house should be no longer delayed. The statement, then, of the Lords' Committee reveals and establishes the fact of the failure of the voluntary system in relation to the general hospitals of London. The evidence does not indicate the exact causes of this failure, if they can be ascertained, but it clearly shows that there is something radically wrong in a system of management which takes no effective steps to prevent its being injurious to the sick poor. It is to be regretted that their lordships, with this failure before them, did not examine more closely into the system adopted in the Poor law infirmaries, so as to bring them more into harmony with the general hospitals. This can easily be done by extending the principles of management of the former, robbed of their indefensible harshness in the working of that portion of the Poor laws which compels temporary poverty from sickness to be regarded and treated as destitution. This is moreover, the origin of one of the chief abuses of the voluntary system—that of affording gratuitous relief to many who have no claim to it from want of means or any other cause. It is a part of the old fallacy of the immorality of State aid in charity as compared with private benevolence for the same end, which latter is infinitely more abused and demoralising, and a much greater enemy to thrift than the former. Their lordships declined, however, to

MAP OF CALAIS

THE CHANNEL

Dotted line old sewers. Thick line new sewers.

by examining the accompanying map, the sanitation of the town is still very imperfect. Under such circumstances it is not surprising that some cases of cholera should have occurred at Calais during the autumn. These cases fortunately were not numerous, probably about seventy in all, but they suffice to demonstrate the danger that besets a town which is situated on the high road of international communications and which is yet so imperfectly drained. Whatever may be the number of cases of cholera, and thus, even where the most careful record is kept, can never be very satisfactorily ascertained, there were, according to M. Cuisinier, the "doctor for epidemics," twenty-four deaths due to cholera. Cholera is supposed to have been brought to Calais by some fishermen from Portel, a suburb of Boulogne sur Mer, and it seems very probable that Portel was infected by excursionists from Paris. Towards the end of September a fishing smack arrived at Calais from Portel with a youth, an apprentice, ill on board. The authorities at Calais did not feel disposed to take charge of the patient, and the skipper of the fishing boat was forbidden to bring him into the town. The skipper consequently hired a carriage and drove the sick youth from Calais to Boulogne. As cholera already prevailed in the latter town, the patient was properly nursed and he recovered. The skipper, having thus successfully disposed of his apprentice, now returned to Calais and was staying in the town when he in his turn was attacked by cholera. The case was so serious that he had to be taken to the Calais hospital, where he died. Thus apparently was the first death due to cholera at Calais. I made some inquiries, but could find no trace of the carriage which had conveyed the skipper and his apprentice to Boulogne, nor was there any record to show that it had been disinfected. When, however, the skipper himself died in the Calais hospital the authorities awoke to the gravity of the situation. They seized his boat, and to ensure its thorough disinfection had it sunk in the harbour. It was not till ten days later, and in the month of October, that another case occurred. The victim this time was a native of Calais. He lived in a cellar in the Rue des Pèlerins, one of the worst and most miserable streets of the old town, situated near the moat of the citadel and not far from one of the principal sewer outfalls. This man was a rag picker, but he had nothing to do with imported rags. He merely went about picking up any rags he could find in the streets of Calais. He was taken with his wife to the hospital, and the next day the authorities, being duly impressed by the dirty, overcrowded and insalubrious nature of the house in which this man had lived, ordered its immediate evacuation. The French law is peculiar and perplexing. In such cases it gives the mayor the power to do everything, but does not stipulate that he shall do anything. The matter practically is left to the discretion of the mayors, and as a result they very generally refrain from touching the property or interfering with the liberty of their electors. But under the stress of a cholera scare they will sometimes take very extreme measures, though to prevent, for instance, a small pox epidemic they would hesitate to take any precautions whatever. In the present instance the mayor of Calais not only ordered the twenty-four tenants living in the infected house to at once leave the premises, but he requisitioned a house wherein to lodge them all. At first the owner of this house consented, but afterwards he refused. The authorities, however, did not care whether the owner of the house consented or did not consent. Availing themselves of the absolute powers conferred on the mayor in such circumstances they requisitioned the house—that is to say, they took forcible possession of the premises. Of course the owner will be compensated and will probably receive whatever sum he may choose to ask. It does not matter much if for the few weeks the house was utilised an exaggerated rent be paid. What is really important in this matter is the fact that the mayor was able, without the loss of an hour, to do what was necessary. Here was a cholera den occupied by twenty-four tenants. Legal difficulties did not occasion any loss of time, the nearest and most convenient empty house was requisitioned, the tenants were put in that house and were kept there for fifteen days, whilst the infected house was undergoing thorough disinfection—whitewashing, repairs &c. But just at the moment that the removal of the tenants was taking place the son of the rag picker fell ill, so he was sent to the hospital and the entire family was also sent to a special ward of the hospital where they were kept under observation.

Thus only the other tenants went to the requisitioned house. In the same evening the rag picker's daughter in law and her child were in their turn seized with cholera, whilst they were under observation at the hospital which they had entered but a few hours previously. The rag picker, his wife and his son, died from cholera, his daughter in law and grandchild alone recovered. Thus there were five cases in the one family resulting in three deaths.

This happened at the extreme north west of Calais, the next case occurred some two or three miles away to the extreme south west of the town, and the victim was also a rag picker. These persons were all extremely poor, loungers about the port, picking up a precarious existence in a variety of ways, and notably by selling whatever old rags they could find. The second rag picker also died. The next two cases occurred on board fishing boats anchored in the port. It will be noted that in the small inner port called the *Bassin de Paradis*, or the Paradise Dock, there are three deaths marked. In my previous articles on the sanitary condition of Calais I insisted at length on the abominable condition of this little dock, or rather it should be called an inner tidal port. I described the bad old sewer that fell into the Paradise Dock. The accompanying map gives the course followed by this old sewer. As there is but a slight current from this dock to the outer port, and thence to the sea, all the slime floating particles, dirt &c. brought down by the sewer are deposited at the bottom and not carried away to sea. When the tide runs out the filth is laid bare and an abominable stench results. Further, I related that the town authorities wanted to dredge up all this filth and carry it out to sea, but the fishermen strongly objected. They maintained that the sewer deposits made a soft bed for their boats to rest upon when the tide was out and the dock dry. It was urged that, though soft, the mud was composed of dangerous filth. The fishermen, however, altogether failed to appreciate this objection, they valued their boats more than their health and would not hear of any measures that would tend to harden the bottom of the port on which their boats rested when the tide was low. Even now that three deaths from cholera have occurred among the crews who were taken ill while on board these boats, nothing has been done to clear away the mud deposited by the sewer in the Paradise Dock. In my previous accounts of Calais I also described the Courgain district, the fishermen's quarter which lies just between this dock and the lighthouse. The little houses in the narrow streets of this district have no closets, and in the centre there is a sort of kiosk where the inhabitants empty their pails every morning, whilst the slop water drains away by the gutters to the new sewer that runs through the centre of this district. Though the inhabitants keep their houses clean, still this is an overcrowded and unwholesome quarter, and, according to M. Cuisinier, was the quarter that suffered most from the cholera, though I only know of two deaths having occurred here. It was in the Courgain district that a slight riot took place. Some patients were forcibly removed to the hospital; and, as they had money enough to pay for medical attendance and to nurse themselves in their own homes, the neighbours considered that they were treated with unnecessary harshness. A crowd gathered, angry cries were raised; but when the patients returned a few days later from the hospital this angry feeling subsided. The patients explained that they had been placed in a new, well aired wing of the hospital, that they had been well nursed by Sisters of Mercy, who had been sent from Paris because they were experienced in the treatment of cholera, and that they had good medical attendance. Also it was found that rich and poor were treated alike and thus the unfavourable impression is dying out.

Though there were more cases in the old town, near the Bassin du Paradis and the Citadelle Mont, still cholera broke out in all the four quarters of the town. The first death took place at the end of September, then there were four deaths in October, eight in November and eleven in January. At the same time it is curious to note, the general death rate in the town during these four months has been considerably below the average. The dots on the accompanying maps show where most of the patients who died from cholera had lived. The two dots at the hospital represent the Sister of Mercy and the male nurse, who both died in the fulfilment of their duty. The map also gives the course followed by the old and the new sewers. The small white dots represent the old sewers and the broad white lines the new sewers. It will be seen that nearly all these sewers have their outfalls into canals. Of

every case where an oath is required by law and for every purpose, the Scotch form must be administered if the person 'desires' to be so sworn." The mere expression of the desire is sufficient, and any inquiry into the person's reasons for desiring it is illegal. The concluding words of the section are 'and the oath shall be administered to him in such form and manner without further question.' The remainder of the article is devoted to clearing up the doubtful point as to whether the Scotch oath could be administered by those authorised to administer an oath in England. After quoting from Section 1 of the Commissioners for Oaths Act, 1889, and reading it with the Oaths Act of 1883, the writer observes: "Can it be reasonably doubted that the power conferred by the two sections of the Commissioners for Oaths Act 1889, which we have quoted, 'to administer any oath,' was intended to include the Scotch form of oath which had been previously prescribed? We do not think it can." The article concludes by reiterating that if any witness, jurymen or deponent attends in any English court, or on any inquiry or inquest, or before an examiner, arbitrator, referee or umpire, or commissioner for oaths, or any one having power to administer oaths, and such person expresses the wish to be sworn in the Scotch form described above, he has a legal statutory right to be so sworn without any question being asked him for all purposes for which an oath is or may be lawfully required. The same rule, moreover, must be applied to promises or oaths of all kinds. Whether all those who preside in our law courts will agree as to the form in which the Scotch oath is to be administered remains to be seen. But it is unlikely that any difficulty will be placed in the way of witnesses wishing to be so sworn, or that any questions will be asked now that their illegality has been shown in legal as well as in medical papers. Medical witnesses are modest and respectful in their bearing towards legal officials, may they always continue so. But they are entitled to every reasonable courtesy and consideration from the latter, and it is to be hoped that we shall not hear of any more questions being asked of anyone wishing to be sworn with uplifted hand.

THE ACTION OF LIGHT ON BACTERIA.

In *Nature* there has been published a report of Professor Marshall Ward's experiments on the action of light on the bacillus anthracis, in which corroboration of some of the more important points as to the action of light on micro-organisms is brought forward.

Professor Marshall Ward's experiments appear to have been carried out with considerable care and with a certain number of control experiments. His method of procedure was to incubate gelatine or agar agar with spores of bacillus anthracis to pour the fluid medium into Petri's dishes and allow it to set to form a plate, then to fix a stencil plate on the under surface of the dish and cover the whole (with the exception of the letter in the stencil plate) with black paper, he then exposed the plate either directly or by means of a reflecting mirror to the action of December sunlight so that the light could only act on the gelatine or agar agar exposed through the stencil letter. Two of his plates, kept for eighteen hours in a drawer and then exposed for five hours, had colonies developed all over the surface, except on that part which had been exposed to the light through the letter where the medium remained perfectly clear, giving sharply marked letters in both cases. In this case, Professor Marshall Ward thinks, the spores were acted upon just at the time they were germinating and therefore during their most tender period, so that they were killed off very perfectly and rapidly. In other cases the line of demarcation was not so distinctly seen, the margins of the letter and the spores there sown receiving reflected rays from the glass cover of the plate. The general result of his experiments was that the actinic rays of light, quite apart from the heat rays, act as germicidal agents.

Professor Marshall Ward's method of demonstrating the result obtained indirectly by Engelmann and directly by other observers is an exceedingly telling one. Even though but few of the Fellows of the Royal Society were able to appreciate the importance of the demonstration most of them must have been struck by the ingenuity with which it was devised. Professor Marshall Ward's general results agree with those obtained by Downes and Blunt and by

Tyndall, the latter of whom, although he failed to prove that germs were destroyed by sunlight, was nevertheless able to show that their vitality was very markedly interfered with. In France, where this question has had considerable attention paid to it by Arloing, Nocard, Duclaux, Straus, Roux and others, it has been proved most conclusively that light has a direct germicidal action, not only in the case of the anthrax bacillus, but also in that of various other species of micrococci and bacilli, and some years ago it was pointed out that light might be made to play a very important part in the attenuation of the virulence of anthrax vaccine. It has, however, been insisted on by some observers that the action of light is not altogether a direct one, but that light acts indirectly by altering the medium in which the organism is growing and quite recently Duclaux has again returned to the attacks on these lines, he holding that under the action of light there are developed in almost all the nutrient media with which we are in the habit of working, certain substances which, even when present in very small quantities, exert a very powerful germicidal influence.

The recent observations made by Koch on the action of direct sunlight in killing the tubercle bacillus, even in the space of a few minutes and regularly in two or three hours, Roux and Yersin's experiments on the action of light on the diphtheria bacillus, Buchner's, Janowski's and Geisler's experiments on the typhoid fever bacillus are all of very great interest, the two latter observers finding that the parts of the solar spectrum and the spectrum of diffused sunlight were far more active in preventing the growth of organisms and determining their death at the violet than at the red end, whilst Geisler has found that similar results might be obtained even when the electric light is used, especially with the violet rays of its spectrum. Of course the more delicate experiments were done, as Tyndall's earlier experiments were, by noting the restraining action of light on the development of the various microbes used rather than by determining the actual death of the organism. Another very important point recently demonstrated, but one often hinted at and even noted before, is that observed by Momont, who found that dry anthrax spores might be exposed with impunity to the action of light for a very considerable time, whilst moist spores exposed to sunlight for forty eight hours in the presence of oxygen were so devalued that they could not grow at all. Bacilli without spores under similar conditions were deprived of their vegetative activity by exposure to sunlight in from one to two hours or even less, but in the absence of oxygen very long exposure—forty to fifty hours—was not sufficient to prevent them germinating when introduced into a suitable medium.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Health of the County of Worcester 1891—The report of Mr Fosbroke, the county medical officer of health, has just reached us. It takes the form of a digest of the district reports, together with an introduction by the county medical officer. Mr Fosbroke again points out the great desirability of all sanitary authorities putting into print the reports of their medical officers. It appears that out of the forty two reports received by the County Council, thirteen were unprinted, a fact which does much to prevent their due appreciation by the public. Before dealing with the vital statistics Mr Fosbroke, very properly, warns his readers to be cautious in the deductions they draw from them, and he enumerates several statistical fallacies by way of illustration. It is much to be regretted that the value of these statistics is somewhat impaired partly by the reason of omissions in some district reports and partly owing to the fact that the census details as regards the rural districts, were not available at the time of making the report. In the urban district of the county the death rate amounted to 18.5 per 1000 but that for the rural districts is not given. The zymotic death rate varied from 0.3 to 2.3 in the urban and from 3.0 to 3.7 in the rural districts. The highest infantile mortality amongst the urban districts was that of Bewdley, where it reached the high figure of 266 per 1000 births while amongst the rural districts Worcester heads the list with

course the water is occasionally drained out of the canals, but only occasionally. The canals are below the high tide level, the water can only be drained out of them at low tide, and the water from the canals can leak into the subsoil of the towns. These canals communicate with the Belgian canals, and a large number of the cases of cholera which have occurred in Belgium have occurred on board barges and on the banks of canals. But, without going so far as Belgium, the canals are sufficiently contaminated in Calais itself. There are two sewer outfalls just by the hospital, one a little further off towards the outskirts of the town, another where the Marek canal joins the Calais canal, and three sewer outfalls in the canal or moat that goes round the citadel. Numerous locks shut up all this sewage and keep it stagnant for many hours, so that it is deposited at the bottom of the canals, engenders foul gases, and permanently poisons the water. The sewers receive all the slop and rain water of the town. The streets that have no sewers drain into the gutters and these gutters flow to the streets where there are sewers. Undoubtedly there should be a main sewer constructed into which all the other sewers should have their outfalls. It would then be necessary to build a pumping station by which the whole of the sewage could be sent out of the town to a safe distance. When this is done there could be no objection to abolishing the abominable cesspools and draining everything direct into the sewers. There would then be no further befouling of the waters of the canals and of the port.

The outline of the old historical town of Calais and the new manufacturing district of St. Pierre-les Calais—formerly different communes but now amalgamated into one township—is easily discerned in the accompanying map. The old walls have almost entirely been removed, but the neutral military zone outside these walls, where it was forbidden to build, not to interfere with the range of the guns, still remains and constitutes a broad open space round the old town of Calais which is thus separated from St. Pierre. On this neutral military zone have been built the new docks, the navigation canal, the new town railway station and the new railway line to the port and Maritime Station. At this latter station the Dover boats land their passengers on an open spot swept by the sea winds and separated by the broad port and uninhabited dock buildings from the old town. The railway line, as if fearing some contamination, curves round at as great a distance as possible from the old town and near to the as yet unbuilt districts of the new town. By travelling round the neutral zone, well away from habitations, the town station is reached, and thence the lines branch off to Paris, Belgium or Germany. Thus persons who land from the Dover boat and take the train at the Maritime Station can scarcely be said to enter the town of Calais, they pass through the parks and gardens of Calais and not through any of its streets. Consequently travellers to the Continent need not entertain any apprehension in taking the train at Calais, even should the few cases of cholera which have occurred prove to be only the precursors of a serious epidemic. The railway line and the Maritime Station are too far removed from any likely epidemic centre. There would nevertheless be a danger if the inhabitants of Calais drank well water but the town has an excellent supply of pure water from Guisne known historically as the Field of the Cloth of Gold. This water, brought to Calais in iron pipes is not likely to be contaminated. For further surety, when it was known that there were some cases of cholera at Calais, the crews of the Dover and Calais passenger steamers were forbidden to land at Calais. Under these circumstances the presence of cholera at Calais should not interfere with the traffic of passengers from Dover, through Calais, to other parts of the Continent, but there is no accounting for what panic will do, and in other respects the existence of cholera in Calais must be very injurious to the interests of that port. Consequently it is gratifying to hear that there have been no further cases during the month of January, but the small epidemic which has taken place should serve as a warning.

So far, however, no effort has been made to profit by the existence of cholera at Calais, to urge the claim for further and greater sanitary improvements, yet the subsoil of Calais seems specially subject to contamination. Apart from the system of drainage which allows the slops to travel long distances in gutters before they reach the sewers, and apart from the fact that cesspools must leak more or less, we must take into consideration that the subsoil has been drained during sixteen years by the pumping operations necessary to

carry out the harbour works. In consequence of this pumping, whilst the docks were being built wells in the St. Pierre district were completely dried up. Of late years this district has greatly increased, many new houses have been built, and for these good dry foundations were found. Now, however, the harbour works are finished. After sixteen years the pumping operations have suddenly ceased, with this result that the wells which were dried up are full of water again, and the cellars of new houses, built on perfectly dry soil, are flooded. Not only has the subsoil water returned to the St. Pierre district, but it cannot drain away with the same facility as in former days, because there are the new dock walls that check the natural flow. Some districts are consequently water logged. It has been necessary to pump out cellars and cement their walls, and thus there are houses literally standing in water. Now, if it be considered that above the level of this underground watershed there are numerous sewer contaminated canals, all leaking, it will readily be seen that specific germs could be carried a great distance under inhabited houses. It therefore becomes more and more imperative to prevent the draining of sewers into these canals. It is absolutely wrong to have sewer outfalls into canals of stagnant water. The present cholera scare is an excellent opportunity for demanding a proper and complete system of drainage for Calais. Not only is this absolutely necessary for the security of the inhabitants of the town, but wider interests are at stake, for passenger traffic between England and France through Calais is ever increasing. It amounted to 247,850 persons in 1888, rose to 345,934 during the Universal Exhibition of 1889, and in 1891, a normal year, there were 265,283 passengers who crossed the Channel between Calais and Dover. Such a traffic as this imposes a certain moral responsibility.

SWEARING ENGLISH WITNESSES IN SCOTCH FORM

UNDER this heading there appears in the *Solicitors' Journal* of the 11th inst. a very able article by Mr F A Stringer, author of a work on oaths and affirmations, in which all the difficulties created by the fifth section of the Oaths Act, 1888, are exhaustively dealt with. Mr Stringer is an authority on this subject, and a few extracts from his article will supply the answer to the doubtful point which was left open in the annotation on page 310 of THE LANCET of last week, while confirming those points on which there was no doubt expressed. Allusion is made at the commencement of the article to the friction which is occurring in consequence of the uncertainty which prevails as to the precise meaning and effect of Section 5 of the Oaths Act, 1888. "The demand of witnesses, especially medical witnesses, to be sworn in the Scotch form, as permitted by the section referred to, is becoming general all over the country, and we regret to say the officials in local courts, and magistrates, justices and coroners are quite unequal to the occasion." After referring to the apparent ignorance of the enactment by some officials and the confusion, in the minds of those who know of it, between the Scotch oath and an affirmation the article proceeds. We could mention several other instances which show that great ignorance and confusion of mind exist on this subject. A very strong attitude has been taken up by THE LANCET and the *British Medical Journal*, and, as a natural consequence, doctors everywhere refuse to be sworn by kissing the book, and demand, as they have a perfect right to do, that they shall be sworn in Scotch form. After showing how the difficulties had arisen from the wording of the fifth section, which is fully quoted, and after dealing exhaustively with the Scotch oath and its form and manner of administration, the article proceeds. "Certainly we may say as a matter of opinion if swearing is to be retained in our legal proceedings, the Scotch form of oath appears to us to have more solemnity and dignity about it than our method of kissing a generally greasy looking ancient Testament, which, as a matter of choice, we should have avoided handling." The article next deals with the application of the Scotch form of oath to the requirements of English proceedings, and the absolute right of any person to be sworn in that form is thus upheld. After quoting the words of the section the writer proceeds. "These words can only be construed as meaning that in

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had declined in the preceding four weeks from 28.5 to 21.9 per 1000, rose again to 24.2 during the week ending Feb 11th, and exceeded by 4.3 per 1000 the mean rate during the same period in thirty-three of the largest English towns. The rates in the eight Scotch towns ranged from 16.6 in Greenock and 16.8 in Leith to 26.6 in Glasgow and 29.8 in Dundee. The 682 deaths in these towns included 51 which were referred to measles, 13 to scarlet fever, 13 to whooping cough, 12 to diarrhoea, 9 to diphtheria, 6 to "fever," and 5 to small pox. In all, 109 deaths resulted from these principal zymotic diseases, against 113 and 93 in the preceding two weeks. These 109 deaths were equal to an annual rate of 3.9 per 1000, which exceeded by 2.1 the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 68 and 41 in the preceding two weeks, rose again to 51 last week, of which 19 occurred in Glasgow, 16 in Dundee and 10 in Edinburgh. The deaths referred to scarlet fever, which had been 12, 9 and 10 in the previous three weeks, further rose to 13 last week and included 10 in Glasgow and 2 in Edinburgh. The 13 fatal cases of whooping cough were within one of the number in the preceding week and included 12 in Glasgow. The deaths from diphtheria, which had increased from 3 to 11 in the preceding three weeks, declined to 9 last week, of which 7 occurred in Glasgow. Of the 6 fatal cases of "fever," 3 were recorded in Leith, and the 5 deaths from small pox included 4 in Glasgow and 1 in Perth. The deaths referred to diseases of the respiratory organs in these towns, which had been 168 and 159 in the preceding two weeks, rose again to 182 last week and exceeded by 36 the number in the corresponding week of last year. The causes of 52, or nearly 8 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin, which had declined from 34.6 to 25.1 per 1000 in the preceding four weeks, further fell to 24.3 during the week ending Feb 11th. During the first six weeks of the current quarter the death rate in the city averaged 29.2 per 1000, against 24.6 in London and 24.9 in Edinburgh. The 163 deaths in Dublin during the week under notice showed a decline of 5 from the number in the preceding week, and included 4 which were referred to "fever," 1 to measles, 1 to scarlet fever, 1 to diarrhoea, and not one either to small pox, diphtheria or whooping cough. In all, 7 deaths resulted from these principal zymotic diseases, equal to an annual rate of 1.0 per 1000, the zymotic death rate during the same period being 1.9 in London and 2.9 in Edinburgh. The deaths referred to different forms of "fever," which had been 11, 6 and 8 in the preceding three weeks, declined to 4 last week, a lower number than in any week since the end of last year. The fatal case of diphtheria was the first recorded in the city since the middle of December last. The 163 deaths registered in Dublin last week included 35 of infants under one year of age and 38 of persons aged upwards of sixty years, the deaths of infants considerably exceeded those recorded in any recent week, whilst those of elderly persons showed a further decline. Three inquest cases and 5 deaths from violence were registered, and 66, or more than a third, of the deaths occurred in public institutions. The causes of 16 or nearly 10 per cent., of the deaths in the city last week were not certified.

THE SERVICES

MOVEMENTS IN THE MEDICAL STAFF

BRIGADE SURGEON LIEUTENANT COLONEL MACARTNEY has arrived at Malta from Gibraltar to complete a tour of foreign service. Brigade Surgeon Lieutenant-Colonel Greenhill has arrived home from India to retire. The following officers have arrived from India in the *Euphrates*—Surgeon Captains Brown, Manders and Durant. Surgeon Captain Nells has embarked in the above troopship for a tour of service in India. Surgeon Captain Lane has been posted to the North British district. Surgeon Captain Morris has returned to Netley from Ceylon where he proceeded in charge of duties.

ARMY MEDICAL STAFF

Surgeon Lieutenant-Colonel Henry Waghorn, from half-pay, is placed on retired pay, Surgeon Lieutenant-Colonel William Finlay retires on retired pay. The undermentioned Surgeons on probation to be Surgeon Lieutenants—Frederick Meredith Mangan, Charles Edward Pollock, William James Taylor, M.B., Bell Wilmott Longhurst, John Herbert Rivers, Henry Arthur Berryman, Ferber Richard Buswell, Frank Albert Symons, M.B., John Henry Farmer and Charles Thomas Samman.

INDIA AND THE INDIAN MEDICAL SERVICE.

The following appointments have been made—7th Bengal Cavalry Surgeon Captain A. G. Hendley, to the Officiating Medical Charge of the Regiment, vice Surgeon Captain J. M. Crawford. 13th Bengal Lancers Surgeon Captain C. H. Bedford to the Officiating Medical Charge of the Regiment, vice Surgeon Major W. Conry. Surgeon Captain A. H. Nott, Officiating Civil Surgeon, Birbhum, to act as Civil Surgeon of Hazaribagh. Brigade Surgeon Lieutenant-Colonel D. F. Bateman, I.M.S., Principal Medical Storekeeper, Madras, to officiate, with the temporary rank of Surgeon Colonel, as Principal Medical Officer of a District in the Madras Command, during the absence of Surgeon Colonel W. H. Roberts, on leave. Surgeon Major T. B. Moffit to have Medical Charge of the Barrackpore Subdivision, in addition to his own military duties, vice Surgeon Captain G. B. French. Surgeon Major R. Pemberton is appointed to act as Civil Surgeon, Cochin, during the employment of Surgeon Major J. W. Evans on other duty. Surgeon Colonel F. B. Scott, M.D., C.M.G., Medical Staff, is brought on the Administrative Medical Staff of the Army, vice Surgeon Colonel A. Allan, deceased. Surgeon Captain L. F. Childe and Surgeon Captain T. D. C. Barry have respectively delivered over and received Charge of the office of Professor of Chemistry at the Elphinstone College, Bombay. Leave has been granted to Surgeon Lieutenant-Colonel F. C. Nicholson, M.B., Civil Surgeon, Patna (p.a.) for 1 year and 324 days, and to Surgeon Lieutenant-Colonel W. A. Gilligan, I.M.S. (m.c.), for six months.

NAVAL MEDICAL SERVICE.

The following appointments are announced—Fleet Surgeons Henry T. Cox to the *Royal Arthur* (dated March 2nd, 1893), Alfred T. Corrie to the *Excellent* (dated Feb 19th, 1893). Staff Surgeons James W. T. S. Kellard to the *Malabar* and Leonard K. Kellett to the *Invincible* (both dated Feb 19th, 1893). Surgeons Geo. H. H. Symonds and Robley H. J. Browne to the *Royal Arthur*, James L. Smith to the *Jachal* and Thomas E. Honey to the *Warpite* (both dated March 2nd, 1893), Edward R. D. Fasken to the *Wye* and Alexander G. Andrews to the *Duke of Wellington* (both dated Feb 11th, 1893). Surgeon and Agent Cecil A. P. Osburne, at Hythe (dated Feb 11th, 1893).

VOLUNTEER CORPS.

Rifle 5th Volunteer Battalion the Royal Scots (Lothian Regiment) Surgeon Lieutenant W. Young, M.B. to be Surgeon Captain—2nd (the Weald of Kent) Volunteer Battalion, the Buffs (East Kent Regiment) Surgeon Lieutenant A. S. Wood resigns his commission, also is permitted to retain his rank, and to continue to wear the uniform of the Battalion on his retirement.—7th (Clackmannan and Kinross) Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders) Surgeon Lieutenant T. Milne, M.D., to be Surgeon Captain.

DEPUTY SURGEON GENERAL E. W. YOUNG M.D.

Deputy Surgeon General Young, late King's Royal Rifle Corps who died on Feb 1st at Southsea served throughout the Eastern Campaign of 1854-55, including the battles of Alma, Balaklava and Inkerman the siege and fall of Sebastopol, and the expedition to Kertch, receiving the medal with four clasps and Turkish medal. He also served in the Indian Campaign of 1858-59, and with the 1st Battalion 60th Rifles on the Red River Expedition of 1870.

HONORARY SURGEONS TO THE QUEEN

We have to congratulate Inspector General of Hospitals and Fleets James John Louis Donnet, M.D., who has been appointed. Honorary Physician to Her Majesty in the vacancy created by the decease of Inspector General David Lloyd Morgan, and Inspector General James Nicholas Dick, C.B., Director-General of the Medical Department of the Navy, who has been appointed Honorary Surgeon to Her Majesty in the vacancy created by the appointment of Inspector General

a rate of 235. There were at the end of 1891 two sanitary districts in the county—those of Stourbridge (urban) and Tewkesbury (rural)—which had so far declined to adopt the Notification Act, but we hope that by this time they have been added to the list, and that the county has in this respect been made complete. During the year five of the authorities have provided isolation accommodation, but there are still twenty-two districts without any proper provision for patients of all classes. As regards sanitary administration in the county, Mr Fosbrooke tells us that the Housing of the Working Classes Act, 1890, has not been put into proper operation and that only one "closing order" has been received. We hope to hear in the next report that the county council has made use of the powers conferred upon it by Section 45 of the Act. Eighteen localities are enumerated in the report as possessing defective sewerage, as also are some sixteen with bad water supplies. County sanitary by-laws are said to be under consideration. The report is one which cannot fail to be of value to all those in the county who are interested in public health.

Padsey Urban District for 1892.—The estimated population of this district in the middle of 1892 was 13,590, the death rate for the year (which is stated to be the lowest on record) was 16.63 per 1000, and the zymotic death rate 1.03. The infantile death rate was 153 per 1000 births. The question of a proper system of sewers for the district is now receiving attention, and Dr Hunter is pressing upon the urban sanitary authority the desirability of providing at the same time proper subsoil drainage. Dr Hunter advocates the more frequent cleansing of the privy middens, which seem to prevail widely in the district, and this is a point which should no doubt—in view of the cholera prospects—receive immediate attention. Owing to the prevalence of tubercle amongst the cattle of the district, particular attention was paid to the cowsheds, the sanitary condition of which appears to be far from what it should be. The importance of a speedy improvement in this direction is still further accentuated by the fact that a large quantity of Padsey milk is sold in Bradford and Leeds. The water supply of the district possesses, Dr Hunter reports, two serious defects—its cost and the fact that it takes up lead from the service pipes, it appears that several of the many samples of water analysed yielded as much as 0.7 grain of lead per gallon. The report concludes with some excellent recommendations to the urban sanitary authority, and we hope they will be adopted.

Leeds Urban District for 1891.—Dr Spottiswoode Cameron issues for the year 1891 a very full and interesting and exhaustive report, and we regret our space will hardly permit of our noticing it as fully as it deserves. The death rate for the year was 22.91 per 1000, which shows an increase of 0.20 on that of 1890 and of 1.75 on the rate for the quinquennium 1885-9. This excess is no doubt due in large part to influenza and its sequelae. Compared with the general death rate of the twenty-eight large towns Leeds shows an excess of 0.36, but when, as Dr Cameron points out, the comparison is made with other towns of the United Kingdom which have a population of over 250,000, Leeds is found to stand fourth on the list, the healthier towns in order of merit being London, Edinburgh and Birmingham. The death rates of the different municipal wards of the borough varied from 16.9 in Headingley to 32.4 in East Ward. The zymotic death rate was 2.41, which was practically the same as in 1890 and 0.37 below that of the quinquennium 1885-9. The infantile death rate was 177 per 1000 births as compared with 175 during the previous year. A large part of the report is devoted to a detailed consideration of special and zymotic diseases and exhaustive tables are given showing the age and sex incidence of each disease, together with the sanitary condition of the houses attacked. Dr Cameron gives a full account of the limited outbreak of small pox which occurred in the borough during the autumn of 1891 and he refers to the way in which the difficulties of tracing the cases are enormously increased by the absence of compulsory notification. It is interesting to note that of 123 persons sent for observation to the sanatorium nine developed small pox. Dr Cameron, at the conclusion of his elaborate report, which to be appreciated must be read, expresses a hope that his committee will before long avail themselves of the increased facilities offered by recent legislation for dealing with infectious diseases—a hope which Leeds will surely endorse.

Stapleton Urban District.—During the year 1892 the death rate in this district was 17.5 per 1000 and the zymotic rate 1.209. The infantile mortality was 140.4 per 1000 births as

compared with 161.6 for 1891. Dr Brown tells us that in connexion with some cases of diphtheria he found the most serious insanitary conditions, and he further draws attention to the indifferent character of the water supply of the district. It appears that all the samples of water submitted to him for analysis fell far short of the required standard of purity, a fact not altogether surprising when we learn that the water is derived from shallow wells. Dr Brown complains of the condition of the cowsheds, where there seems to be considerable overcrowding and defective drainage. We are glad to hear the sewers have been extended, but wish the report held out prospects of a proper water supply.

Actterton Urban District.—The population of this district has increased considerably during the last two years, and is now estimated at 21,000. The general death rate for 1892 was 16.1 per 1000, and the zymotic death rate only 0.6, while the infantile mortality, which, as Mr Dryland observes, is much too high, amounted to 154 per 1000 births. The number of deaths from phthisis has been gradually diminishing for some years, and this is attributed in great measure to the improved condition of the factories. We notice with regret the existence of twenty-five cases of typhoid fever during the year. The report states that the Notification Act "has worked exceedingly well and without the least friction", and it is gratifying to hear that the infectious diseases hospital is proving a success. A plentiful and good supply of water has been obtained, and steps are about to be taken to purify the sewage effluent. A record of work done by the inspector of nuisances is annexed to the report, and shows evidence of zeal and energy.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN thirty-three of the largest English towns 6819 births and 3934 deaths were registered during the week ending Feb. 11th. The annual rate of mortality in these towns, which had declined in the preceding five weeks from 29.2 to 20.2 per 1000, further fell last week to 19.9. In London the rate was 19.1 per 1000, while it averaged 20.4 in the thirty-two provincial towns. The lowest rates in these towns were 14.9 in Wolverhampton, 15.4 in Cardiff, 15.5 in Huddersfield and 16.1 in Nottingham, the highest rates were 22.3 in Blackburn, 22.8 in Liverpool, 23.7 in Preston, 24.1 in Manchester and 25.9 in Bradford. The 3934 deaths included 361 which were referred to the principal zymotic diseases, against 396 and 351 in the preceding weeks, of these, 91 resulted from whooping cough, 80 from diphtheria, 73 from measles, 43 from diarrhoea, 41 from scarlet fever, 21 from "fever" (principally enteric) and 12 from small pox. No fatal case of any of these diseases occurred last week in Burnley, in the other towns they caused the lowest death rates in West Ham, Swansea, Wolverhampton and Sheffield, and the highest rates in Portsmouth, Salford, Plymouth, Derby and Bolton. The greatest mortality from measles occurred in Brighton, Portsmouth, Plymouth, Bolton, Hull and Newcastle upon Tyne, and from whooping cough in Derby, Salford and Gateshead. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 80 deaths from diphtheria included 62 in London, 3 in Manchester, 2 in Cardiff, and 2 in Birmingham. Three fatal cases of small pox were registered in Manchester, 2 in Salford, and 1 each in London, Liverpool, Leicester, Derby, Oldham, Halifax and Leeds, 106 cases of this disease were under treatment in the Metropolitan Asylum Hospitals and 22 in the Highgate Small pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2513, against 2774, 2688 and 2580 on the preceding three Saturdays, 257 new cases were admitted during the week against 250 and 255 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had declined from 984 to 452 in the preceding four weeks, further fell to 377 last week and were 93 below the corrected average. The causes of 90, or 2.3 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Croydon, Cardiff, Bolton, Oldham, Blackburn and in eight other smaller towns, the largest proportions of uncertified deaths were registered in West Ham, Brighton, Birmingham, Halifax and Hull.

"SENSITIVENESS OF THE PERITONEUM"

To the Editors of THE LANCET

SIRS.—As no circular letter has reached me from Mr Lawson Tait's secretary on the subject of the "Sensitiveness of the Peritoneum," I may infer that as far as Birmingham is concerned I am not one of those "whose names are familiar in connexion with abdominal work." Nevertheless I have had the experience of a considerable number of years, extending to hundreds of cases of ordinary abdominal section, and probably a unique experience amongst "the surgeons of Great Britain and Ireland" in vaginal hysterectomy, and I shall feel obliged to you for the opportunity of expressing my opinion on the subject under discussion. I should like also to call attention to one point in particular that has arisen incidentally in the debate on this subject and in vivisection. Many years ago in one of my first cases of oöphorectomy, which I reported at the time in a paper read at the Manchester Medical Society protrusion of the intestine occurred owing to the snapping of bad material employed in suturing the abdominal wound. My attention was called to the case a day or two before I would otherwise have interfered with the dressings owing to the fact that these were observed by the nurse to be stained with red serum. I undid the dressings and, to my horror, found a large knuckle of intestine protruding and adhering to the lint, and it required a good deal of swabbing and picking and other manipulations to clear the bowel from the dressings. To my surprise the patient hardly winced, and it was only after putting the bowel back with a soft sponge and proceeding to introduce silk sutures through the abdominal skin that she made any outcry. The patient recovered without any further incident. More recently, owing to an omission on the part of a nurse, I have had to deal with a case of obtrusion of intestines, and I dealt with the "accident" in the same way, without waiting for the administration of an anæsthetic.

It seems to me to be the external wound that is painful. This is not a mere impression, but is an opinion formed by observation in dealing with the wound in cases in which a drainage-tube had been prematurely removed or in which a drainage-tube had not been introduced at the time of operation. This opinion is supported by my experience of vaginal hysterectomy. In my first thirty to forty cases I did not suture the chasm left in the floor of the pelvis by the removal of the uterus. The intestines were sometimes pushed very low in the pelvis by the straining permitted by imperfect administration of the anæsthetic, and sometimes the bowel and omentum were dragged down in removing the sponges. In the first dressing of these early cases the bowel had to be supported on a pad of iodoform gauze, and every successive dressing entailed more or less interference with the peritoneum and intestine. In these cases the element of interference with a painful external wound was eliminated. After the introduction of the vaginal specula and the full exposure of the wound in the pelvis—a proceeding which was always painful the first few times—the manipulation of the pelvic contents could be carried out with little or no complaint from the patient. With suitable forceps the intestine and omentum could, when necessary, be swabbed with pledgets of cotton wool and even pushed further up whilst the patient appeared to be unconscious of the proceedings. If, however, the ligatures on the broad ligament were pulled upon, there was immediately some expression of suffering.

There is a class of phenomenon in connexion with the introduction of the blandest of fluids or of the blood of the patient into the peritoneal cavity, which Mr Lawson Tait refers to, about which I have formed no theory and which I do not understand. In flushing the peritoneal cavity I use a solution of common salt, which is less irritating, and for other reasons more serviceable than boiled water, yet at the first or second dressing when a drainage tube is used the introduction of a small quantity of the solution (temperature 100° F) in order to keep effused blood in solution often gives rise to severe pain. It might be objected here that there is some carelessness about the temperature, but how then can we explain the cases in which the patient's own blood, gushing into the peritoneal cavity—as for example, when rupture occurs in tubal pregnancy, gives rise to intense pain? In one case, otherwise uncomplicated on which I operated the patient after her recovery described the onset very graphically. The pain was so sudden and so agonising all over the abdomen that she could not help the practitioner who first saw her in localising the

site of its origin, and, in fact, to some extent she misled him. If space will permit, will you now allow me to refer to a matter which I expected some one would have called attention to ere now in connexion either with the present or a recent controversy? In his paper in THE LANCET of Jan. 21st Mr Lawson Tait again gave expression to an eccentric opinion. "I think the facts as they are substantiated by many of my correspondents show that here as elsewhere it is perfectly impossible to accept the conclusions derived from experiments on animals as applicable to man." He also added "It is probable also that it is dangerous to accept the conclusions derived from one human patient as applicable to another of the same kind." If such a position were tenable there would be an end to all experimental research in biology, and even biological science would be impossible. Might a controversialist in a difficulty with the chemists not as well hunt at his want of confidence in the regular behaviour of the atomic weights of the elements? I think Mr Lawson Tait should give some reasonable explanation of the statements which he recently published in reference to his attitude in the vivisection question and some passages in his most recent bound book. He threw over the "women and clergymen" in alleging that he did not object to experimental research in biology on sentimental grounds, but because inferences could not be drawn from such work which could be of any value as applicable to man, and yet if anyone interested will turn to "Diseases of Women and Abdominal Surgery," vol. 1, he will find the chapter on the Theory of Menstruation curious reading in the light of recent statements by the author Mr Lawson Tait. He draws largely upon two papers contributed to the Transactions of the British Gynecological Society by Mr Bland Sutton and Dr Arthur W Johnstone of Kentucky, and he refers to them in terms of extravagant praise. They are both "brilliant researches" and Dr Johnstone's becomes "the most brilliant contribution to this subject which this century has seen" (p 326). But will it be believed by your readers who may be unfamiliar with this class of subject that the essay so characterised by Mr Lawson Tait depended for some of its "brilliant" qualities upon "the researches of Johnstone on the wombs of animals" (p 324)? As for Mr Bland Sutton's paper, read at the same meeting of the British Gynecological Society, in 1886, in which Dr Johnstone's was introduced, it bore the short and uncompromising title of "Menstruation in Monkeys." There may be some simple natural explanation of the praise of these two essays and the latest modification of opinion on the part of the professional champion of the anti-vivisectionists and, if so it will doubtless be forthcoming, but, *prima facie*, the inconsistency appears more suitable to the field of contemporary politics than to that of biological science.

I am, Sirs, yours truly,

Manchester Jan. 30th, 1893

W J SINCLAIR.

THYMOL AS AN ANTHELMINTIC IN FILARIASIS

To the Editors of THE LANCET

SIRS.—Surgeon Lieutenant-Colonel E Lawrie in THE LANCET of Nov 26th reiterates his belief, founded on the experience of two cases,¹ in the power of thymol to cure chyluria and to cause the disappearance of filaria sanguinis hominis nocturna from the blood, contrary to the experience of Surgeon Lieutenant-Colonel A. Crombie² in the case of the same parasite and my own in the case of the closely allied parasites, filaria sanguinis hominis diurna and perstans.³ He further states that Surgeon Captain P Hehr has also succeeded with the drug. Should further experience confirm his results Surgeon Lieutenant-Colonel Lawrie is to be congratulated on a therapeutical discovery of the first magnitude, as those who have studied the subject of filariasis will readily understand. Impressed with the importance of the matter I took an early opportunity of repeating Surgeon Lieutenant-Colonel Lawrie's experiment, this time in a case of filaria nocturna infection. Possibly, I thought, my failure in the case of filaria diurna and filaria perstans might have been owing to insusceptibility to the drug in these specifically different parasites. My experiment was made in the following case—

A man aged twenty one, born in India of English parents,

¹ THE LANCET Feb 14th, 1891.² Ibid. Aug 13th, 1892.³ Ibid., Oct. 1st, 1892.

James John Louis Donnet to be Honorary Physician to Her Majesty

THE TRANSPORT OF TROOPS

We are glad to notice that Mr Campbell Bannerman's attention has been called to the discomforts experienced by the Royal Scots Fusiliers during their short voyage on board H M's ship *Assistance*, to which we recently adverted. The War Minister frankly admitted that great discomfort was undoubtedly experienced, but it was in great part attributable to the exceptionally bad weather, the time occupied in the voyage, and the number of men who were prostrated by sea sickness. There was no overcrowding, according to the estimated accommodation, but he was bound to allow that complaints had been received in regard to this vessel on which he proposed to confer with the Admiralty. We can only repeat what we have already pointed out, that as young soldiers are very frequently bad sailors, and as the short voyages made by these coast transports are often exceptionally rough, it is extremely desirable, in the interest of the public service, that the accommodation and arrangements on board should be made as good as practicable.

EGYPT

Now that additions have been made to the army of occupation in Egypt, the total strength of the force in that country will amount to 6000 and upwards. We trust that arrangements will be made for accommodating as many of the men as practicable in suitable positions outside the large towns, and that ample space and ventilation will be afforded to all the troops in barracks during the ensuing hot weather. Our attention has been called to the fact that there are some excellent sites for encampments at a few miles' distance from Cairo, on which it is to be regretted that huts or buildings of a temporary character were not erected years ago. The occupation of some of the barracks at Abbasesh, where the troops could have ample space and ventilation, would probably be preferable to quartering them in some of the barracks in Cairo itself. We need scarcely add that every effort should also be made at Alexandria to diminish the amount of disease which unhappily prevails in the garrison there year after year. The Egyptian Government accounts for the past year continue to show a very satisfactory surplus, notwithstanding the large remissions of taxation that have taken place during the past three years. The general improvement in the Customs and Railway receipts and in the yield of the indirect taxes is evidence of the prosperity of the country. A large saving has been effected by the conversion of the debt, and large reserve funds have been created under our financial administration of the country, consequently there does not appear to be any reason why some outlay should not be incurred in prosecuting public sanitary works and in providing the European garrison with wholesome and healthy accommodation.

EXAMINATIONS FOR SANDHURST

On the last occasion of the medical and literary examinations for admission to the Royal Military College, Sandhurst, the number of candidates was very large. It is understood that, in future, changes will be made in the conduct of these examinations. Instead of London being the only place at which they are held, as has been the practice hitherto, the literary part of the examination will be held in the metropolis and at several other large towns also, and only those candidates who have been successful in this portion of the examination will be subjected to the physical or medical examination as to their fitness for Her Majesty's service. It is thought that in this way the candidates will be spared expense and inconvenience and that the medical officers will be relieved of much unnecessary labour.

THE RECRUITING FOR 1892.

According to an article in the *Standard*, *apropos* of the forthcoming Annual Report of the Inspector General of Recruiting, there would appear to be no doubt that all things considered, the recruiting for 1892 has been more satisfactory than for any year since 1885. It is stated that the number of recruits enlisted in 1892 exceeds 41,000. Of the total number not more than 2500 enlisted for twelve years' service. About one-third probably of the men, however, are "specially enlisted" because they do not come up to the prescribed standards of measurement. Many causes have contributed to this success, the chief of which is probably the greatly increased prospect of civil employment after leaving the colours. The infantry is the only arm of the British Army which is not above its establishment, and it is in this direction that the conditions of service require remedial

measures. The Secretary for War will shortly have to discuss the subject of the report of Lord Wintage's Committee, and we shall then learn which of the number of measures recommended in that report the present Government are inclined to adopt.

Correspondence.

"Audi alteram partem."

"THE PROOF THAT CHLOROFORM HAS NO DIRECT ACTION ON THE HEART"

To the Editors of THE LANCET

SIRS,—It seems to us desirable, after reading the first paragraph of Surgeon Lieutenant Colonel Lawrie's article in THE LANCET of Feb 11th, to briefly state the circumstances under which we carried out an investigation into the action of chloroform. In undertaking to write a report on the work of the Second Hyderabad Chloroform Commission we accepted the assistance of the Nizam's Government, and we distinctly understood that we were engaged in a purely scientific investigation and that the results of the investigation would be given to the medical world, whatever might be the conclusions at which we arrived. Our experiments were carried out, and we sent a draft report to Surgeon Lieutenant Colonel Lawrie in August, 1892, in perfect good faith, for the purpose of obtaining his and Surgeon Major Bomford's criticisms before publication. He acknowledged its receipt and promised to send us back the draft report "in a mail or two" with these criticisms, so that we might modify it as we thought fit. Up to the present we have not received it. A telegram, dated Hyderabad, Oct. 8th, however, appeared in *The Times*, asserting that Surgeon Lieutenant Colonel Lawrie had settled the controversy as to the action of chloroform by means of cross circulation experiments (a method devised by us), and we heard incidentally from Dr Lauder Brunton that a copy of our draft report had been received in London from India, but he was not at liberty to say to whom it had been sent or what was to be done with it. Shortly afterwards Surgeon Major Bomford came over to England and we had the opportunity of meeting him in December last. He had not brought our draft report back with him, but as he had read it, and we fortunately had kept a copy, we were enabled to discuss it with him and to modify it in a few particulars in accordance with information he gave us on some points in the Commission's report and on Surgeon Lieutenant Colonel Lawrie's method of chloroform administration.

Seeing, then, that a copy of our draft report had been sent to some unknown person in London instead of being returned to us as promised, and also that we had obtained from Surgeon Major Bomford all the criticism he had to offer, it seemed to us clear that we were not likely to receive any further criticism from Hyderabad, so we determined to wait no longer and accordingly published our report. We are therefore surprised to find Surgeon Lieutenant Colonel Lawrie quoting from our draft report without our permission. We distinctly understood from the commencement of the work that the publication of the report was in our hands, and Surgeon Lieutenant Colonel Lawrie in acknowledging the receipt of the draft report, said "We shall not attempt to take any advantage of you in the way of publication." We leave the medical world to judge how far Surgeon Lieutenant Colonel Lawrie has at heart the desire to know the truth about the action of chloroform when, if we judge from his behaviour to us with regard to publication, and from the final sentences of the first paragraph of his present communication, it appears that he has done his best to suppress an investigation, initiated by himself, because its conclusions are adverse to his preconceived views.

We are, Sirs, yours truly,

W H GASKELL,
LEWIS E SHORE.

Cambridge, Feb 14th 1893

* * We think it is but fair to Surgeon Lieutenant Colonel Lawrie to state that the copy of the draft report alluded to in Drs Gaskell and Shore's letter was sent by him to us in October last, and is still in our possession. We understood, however, that it was not sent to us for publication.—ED L.

be justified I am ready to overcome my repugnance to them at once.

I can have no sympathy with those who talk such nonsense as to say that men of science ought not to be placed under restrictive legislation. My answer is at once to print to the Anatomist Act and to say that honest anatomists do not object to it and that criminal anatomists brought it about. Dr Klein's evidence alone was enough to convince an reasonable man that restrictive legislation in the matter of dissection was urgently needed.

I am, Sirs, yours truly,

LAWSON TAIT.

Edinburgh, Feb 17th, 1893.

ARE DISEASE GERMS IN MILK DESTROYED BY BOILING?

To the Editors of THE LANCET.

SIRs,—In the early part of 1891 I wrote a letter to THE LANCET saying it was by no means certain that disease germs in milk were destroyed by ordinary boiling and quoted Mr. Watson Cheyne's opinion that, to make sure the milk required to be boiled for from ten to fifteen minutes on three successive days. Dr. Fayer, in the *L'Année Médicale* de Caen, now comes forward and states that he does not believe that the germs are destroyed by boiling. The tubercle bacillus is killed only at a temperature of 110° to 115° C. Experiment made at his laboratory at the Physiological Institute show that the degree of coagulation never exceeds 100° C. Children, he says, die from enteritis and boiled milk is to be feared. I must encourage his assertion. He considers it harmful to children. Another matter about which there is difference of opinion is whether tuberculous can be conveyed to human beings by means of milk from tuberculous cows. Owing to a report it would appear from the Veterinary Inspectors, the Public Control Committee of the London County Council have come to the conclusion that such milk may cause serious mischief to health but from laboratory experiments recently carried out an opinion has been given that it does not cause tuberculous. Surely such important matters as these should not be allowed to remain any longer in doubt.

I am, Sirs, yours truly

F. P. ATKINSON

Nottingham, Feb 14th, 1893.

THE ETHICS OF OPIUM.

To the Editors of THE LANCET.

SIRs,—Having read Dr. Moutat's article in last week's issue of THE LANCET, I see no reason for continuing the controversy. My single motive for personally writing at such length was to show how baseless was the charge which Dr. Moutat had brought against the Anti-opium Circular of December 1891, of being 'a most mendacious document.' I have, I believe, shown ample reason for the statements of the Circular, bringing forward a variety of facts in connexion with India with which Dr. Moutat himself was evidently unacquainted, and otherwise showing abundant cause why at least an expression which conveyed a direct insult to four of his professional brethren should be at once withdrawn. I had hoped that one who professes so great a regard for the correctness of discussion as Dr. Moutat does would have taken this course, and until he does so I have nothing more to say to him.

I am, Sirs, yours truly

JAMES L. MAXWELL, M.D.

Highbury Park, N. Feb 14th, 1893.

THE CONFERENCE ON CHOLERA IN ST PETERSBURG

(FROM OUR SPECIAL CORRESPONDENT.)

(Continued from p. 177.)

THE results of the proceedings of this Conference appear to us only and it will be some time yet before a full account of the proceedings will be published. In the meantime, it appears from conversations with members of the Conference that the general results have been quite satisfactory and in some respects even more so than had been anticipated. The Conference appears to have been carefully organised to carry out the object with which it met. The questions formulated

by the earlier general meetings of the members have been fully discussed by the commissions and sub-commissions and their conclusions have again been presented to the later general meetings for ratification and approval. As stated before, the commissions have held their discussions from ten till three daily, and even in some cases have renewed them after the general meetings of the Conference (held at seven o'clock each evening) and prolonged them far into the night. In this way during the week devoted to the Conference, all the important practical questions have been thoroughly debated by bodies of medical men who may be considered as experts on the particular point submitted to them. Thus one sub-commission, consisting entirely of physicians attached to railways, discussed the measures that have been and should be taken on the railway lines throughout the empire to prevent the introduction or to control the spread of cholera by this means or communication. A second sub-commission was devoted to the discussion of the question of quarantine. These two sub-commissions together formed the Commission constituted to decide the points raised in Dr. Tolstoy's paper on Precautionary Measures directed against the Dissemination of Cholera.

Having spoken above of the practical questions raised by the Conference, it may now be added that all the questions discussed were of a practical character. The many theoretical aspects of the subject do not appear to have come under consideration, or if considered at all, have been treated only as incidental to the decision of some point of practice. The treatment of the disease, as will be shown later, has been briefly reviewed.

The question of quarantine, both by sea and land, was fully debated and certain conclusions were arrived at. Dr. Tolstoy, in introducing the general discussion on this subject, pointed out that some confusion existed as to the meaning of quarantine, the word being often loosely applied to places where detention was not practised, or where merely examination and disinfection were carried out. He recommended the use of the word to those points where detention of the healthier or the person of infection of a threatening epidemic disease is practised, while those points where the examination and disinfection of luggage, the inspection of passengers and the detention of sick alone are carried out should be known, as heretofore, as observation points. The net result of the discussion on this subject has been that the Conference concerned the principle of quarantine as thus defined, and recommended the substitution for it, alike on sea and land frontiers and on the internal lines of communication, of a system of inspection, disinfection and isolation of suspicious cases.

A paper was read by Dr. Uspenski on the Measures taken on Railways a second by Dr. Sakharof on the Measures taken on Waterways and a third by Dr. Yershof on Certain Practical Points in the Medical and Sanitary Services in Districts threatened by Cholera. These papers are not yet in print, but as they led to lively discussions it may be of interest to give the titles of points submitted by one of the writers to be debated in committee, more particularly as they well illustrate the thoroughly practical character of the Conference. Dr. Yershof, in concluding his paper formulated the following questions: 1. What number of medical men are necessary in a given area in relation to the number of inhabitants and taking into consideration the intensity and character of the epidemic? 2. What number of feldshers and attendants (nurses &c.) are necessary for such medical men? 3. Under what conditions are dispensaries necessary and what type should they follow? 4. The carriage of the sick. 5. The conditions under which the sick may be treated at home. 6. To what extent are the rules for disinfection worked out by the Medical Council, capable of being officially carried out, more particularly in villages and country places? 7. To what class of person should be entrusted the carrying out of disinfection? 8. What means have appeared most suitable for disinfection? 9. To what extent has the disinfection of persons arriving from a cholera-stricken locality appeared practicable? 10. To what extent is it possible to substitute the burning of articles for their disinfection, and how could this be organised? 11. By what persons should in future the choice of members of the sanitary service be made? 12. How many such members should be trained in each district? 13. In what kind of medical institution should they undergo

had never been out of India when he joined the army five years ago. He passed a very stringent medical examination and was pronounced healthy in every respect. Eighteen months later he discovered that he had a swelling in the left groin. This continuing to increase and interfering with his efficiency as a soldier, he took his discharge in May, 1891, and came to London for treatment. He was a patient for some time in the London Hospital, where I saw him along with Dr S Mackenzie. There was a large swelling the size of the fist occupying nearly the whole of Scarpa's triangle on the left side. It was prominent, lobulated, soft, painless, obscurely fluctuating, non-adherent to the skin, but not movable on the deep structures. On lying down the swelling somewhat subsided, and when in this position firm pressure with the palm of the hand caused it slowly to disappear. On standing up although pressure was maintained, the swelling gradually reappeared. There was no impulse on coughing. A similar but much smaller swelling existed in a corresponding position on the right side, there was also some obscure fluctuation in the left tunica vaginalis. On thrusting a hypodermic needle into the swelling on the left side a pinkish white, coagulating fluid escaped through the needle in drops and several drachms of the fluid were quickly collected. On placing a little of it under the microscope living embryo filariae were found. Puncture of the left tunica vaginalis gave vent to a similar fluid in which filariae embryos were found in very great abundance. When examined during the night the patient's blood was found to contain filariae. He was evidently the subject of that form of varicose groin glands which is so frequently associated with chyluria, lymph scrotum, chylous dropsy of the tunica vaginalis and filariae in the blood. On the evening of Nov 26th, 1892, I examined his blood along with Dr Wethered. In one slide, containing about one drop of blood, after staining with weak fuchsin and decolourising with weak acetic acid we counted 413 embryo filariae nocturnae. On the 27th he began to take thymol in four grain doses four times a day. He continued to take the drug till Jan 16th. It did not affect his health or comfort in any way. On Dec 6th a small slide of blood drawn at 9 P.M. contained 120 filariae, another drawn at the same hour on Dec 16th contained the parasite in abundance. A full slide examined on Dec 29th contained 359, a fourth slide drawn on Jan 16th, 1893, and which Dr Wethered examined along with me, contained 327 filariae and another drawn at the same time contained 308. In slides of unstained blood the parasites were observed to be active and apparently in no way affected by the long course of thymol. In view of the importance of the subject Surgeon Lieutenant Colonel Lawrie ought to make an extensive series of experiments by which he might either corroborate or upset his statements in regard to the efficacy of thymol in filariasis. Here opportunities are of somewhat rare occurrence, but in India it would be an easy matter to multiply his experiments indefinitely.

I am, Sirs, yours faithfully

PATRICK MANSON, M.B., M.R.C.P., LL.D.

Feb 13th, 1893

UNQUALIFIED PRACTICE

To the Editors of THE LANCET

SIRS,—Your own correspondent at Manchester, at the end of his report on the scandalous case of "unqualified medical practice" at Manchester in THE LANCET of Feb 4th, remarks "If a druggist without medical diploma is to be permitted to conduct a large medical practice, as this man coolly boasts to have done, and if in the course of his trade he improperly attends small pox cases and thus prevents their notification and isolation by the constituted authorities, it is high time that the Notification Act, the Medical Act, or some other statute were so strengthened as to reach such a case." In your annotation you endorse his remarks, and every medical man in the Kingdom will do the same.

There is no question as to the evils of unqualified practice in all its forms, nor can it be denied that the evil is as widespread as it is unchecked. No existing law sufficiently meets the case, the Apothecaries Act is too cumbersome and it would not be fair to expect the Society to act the policeman for the whole profession. The various medical Acts deliberately avoid the issue in question. So far I venture to believe the majority of medical men will be in agreement with me. A great public and professional evil is admitted and the law of the land is not able practically to deal with this evil. It follows that the law requires altering, and the real question

begins as to how it should be done and by whom the Legislature should be approached.

Putting on one side for a moment the public interests, the general practitioners scattered throughout the empire are undoubtedly the chief sufferers, more especially the poorer ones in our great centres. On the face of it, the general body of practitioners are too scattered and possess too little interest in high quarters to combine to carry any Bill through Parliament. The University Senates and the Councils of the Royal Colleges are formed of men who do not have the evil brought under their special notice, and consequently can afford to view the matter without emotion. Moreover, they are not noted for working harmoniously together, and they also are scattered up and down the kingdom. There remains the General Medical Council for Education and Registration. This Council is composed so as to represent the Crown and all the divisions of the medical community. The members are in touch with the Privy Council and in many instances are personally acquainted with our great politicians and law makers. The voice of an unknown person like myself speaking in the wilderness is not likely to penetrate to the ears of these fathers of the profession. It cannot be doubted that it is within the power of the General Medical Council to formulate an amendment to the medical Acts wherein it should be enacted that it was illegal for unqualified persons to prescribe for or treat patients for their own pecuniary profit and to mete out prompt punishment for those who broke the law. These gentlemen alone have the power to approach with any chance of success the government of the day, and as we have for the first time a member of our own profession (Sir Walter Foster) in high office, it would be a graceful act for the Medical Council to make the attempt and show they were alive to the need of pushing outside their present boundaries not only in the interests of the public, but in the interests of the great profession they represent. It is with the hope of inducing the Editors of THE LANCET to use their power in influencing the members of the General Medical Council that I have ventured to write again on this well worn theme and to ask you to point out any alternative method of procedure by which this much needed change in the laws could be accomplished.

I am, Sirs, yours very truly,

Margate Feb 7th 1893.

BERTRAM THORNTON

BRITISH INSTITUTE OF PREVENTIVE MEDICINE

To the Editors of THE LANCET

SIRS.—The skeleton report of a meeting held here on the 2nd inst. in support of the establishment of this institution so incompletely represents what I intended to convey that I must ask you to let me briefly restate my views. They are a matter of such little importance that I am surprised emphasis is laid upon the fact that I left the meeting at all, and still more when it is stated that I left at the commencement of the discussion. I left when I thought the discussion had finished, for there were loud cries of "Vote, vote!" some time before I left, and to be present at all I disarranged my appointments and incurred the discomfort of a midnight journey, because I knew very well that the meeting had an object carefully concealed and quite beyond its avowed scope. What I did say was that I objected altogether to the past record of experiments on animals as delusive, that bacteriological research was a new thing since my student days, that it had unquestionably benefited the brewer and the grower of grapes, that it had possibly conferred benefit in the cases of some diseases of animals, but that in its applications to man I could not admit in a single instance the word "proved" so lavishly used by Dr Ruffer. I therefore yielded to the resolution a reluctant assent, I certainly did not use the words "fully assented."

Thus far I went because I really regarded Dr Ruffer's proposals as reasonable and such as should not be hindered, but it is clear from Mr Victor Horsley's attitude, I was upon this point quite mistaken. I have no intention of continuing this discussion but I should be glad if you would allow me to put myself right on one point. A vast number of illustrations taken from surgical advance have been quoted as illustrations of the value of experiments on animals, and they have been shown, one and all, to be mistaken. I have taken some part in this argument, but between that attitude and a plea for the total suppression of experiments on animals there is a very wide difference, and if such experiments can

NORTHERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENT)

The Fire at the Newcastle Literary and Philosophical Society

On the 7th inst. the Literary and Philosophical Society of Newcastle celebrated its centenary by a brilliant *soirée*, and Lord Armstrong delivered an interesting lecture, with experiments, on electricity. All passed off well but at breakfast the next morning most of our citizens read with amazement that the place had been burnt down. It was not quite so bad as that, however, still the library has been destroyed either by fire or water, and in some respects the loss is irreparable, as it contained many valuable books, prints and manuscripts, duplicates of which could only be found in the British Museum. The fire, it appeared, arose from some temporary arrangements for heating water for the tea used at the *soirée* and broke out at five o'clock. There was no resident on the premises at the time.

Fleming Memorial Children's Hospital

The annual report presented at a meeting of Governors of the Fleming Memorial Children's Hospital, Newcastle, states that a larger amount of work has been done than in any previous year since the hospital was established. The number of children—namely 584—shows an increase of 153 over the number treated in 1891, and 353 over that treated in 1890. The number of operations has risen from 55 in 1890 and 137 in 1891 to 318 in 1892. The average cost of each patient, including all expenses, was £5 10s 1d. Through the kindness of Lady Armstrong the out-door department was still carried on in Hanover square, and there the number of fresh cases has also risen. In addition there were 852 out-patients treated at the Fleming Memorial Hospital. In the report from which this note is extracted there is nothing said about the rate of mortality. It was considered by many as excessive. The drainage and other sanitary defects have been overhauled during the year, the financial state of the hospital is likewise more satisfactory than in the previous year.

Infantile Mortality in the Auckland District

At the last meeting of the Auckland Sanitary Authority one of the medical officer's reports stated that in his district 466 deaths took place. Of these 180 occurred in children under one year of age, more than half in those under five years, 20 succumbed to measles, and 51 to zymotic diseases.

Middlesbrough

At the last meeting of the Sanitary Committee of the Middlesbrough authority Dr Malcomson stated that ten deaths had resulted from pneumonia during the month, and one death was due to influenza, which had been very prevalent in a mild form. During the month eight cases of small pox had been treated at the Fever Hospital. At a coroner's inquest held at Middlesbrough last week on a child the coroner severely reprimanded the father of the child for saving by a series of misstatements seriously imperilled the medical attendant's position and practice, but the doctor, he said, and his locum tenens were entirely free from blame.

A Daring Leap

Last week a member of a performing company in Newcastle leaped from the parapet of the High Level Bridge, a distance of about 130 feet, to the water. On rising to the surface he struck out for the shore, which he reached in safety. He was, it is stated, "a professor" of swimming. I presume the worst of these feats is that they are apt to be imitated by amateurs, who may not fare so well as 'the professor'. A few years ago a workman in a state of drunkenness jumped off the bridge for a wager and survived the insane attempt. About thirty years ago a professional swimmer performed the feat in safety.

February 15th.

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

Infectious Diseases Hospital for Leith

The plans of this hospital, as generally approved by the subcommittee of the Leith Town Council, are on view in the Council chamber. The plans show five wards four of which contain eighteen beds each, whilst the fifth is a probationary

ward with ten beds. The cubic space allowed for each bed is 2028 ft. The wards are to be heated partly by low pressure hot-water pipes and partly by fireplaces. There are a disinfecting house, a mortuary and an administrative block, in which there is accommodation for doctors, nurses, servants and other officials. The total cost, including furnishing, is estimated at over £24,690.

Orders by the Board of Supervision to Leith

The Board of Supervision has issued an order to Leith in virtue of the authority vested in them by Act of Parliament to issue such directions and regulations as they may think fit for the prevention of epidemic or infectious diseases. The order says that whereas directions and regulations extending to the whole of Scotland were issued by the Board on July 21st, 1892 and whereas it is expedient that provision should be made by the local authority for a house to house visitation within the burgh of Leith, therefore in virtue of the authority vested in it the Board orders this to be done. Further, it is ordered that whenever it is found that a dwelling house or other property is a nuisance, in terms of the Act, the local authority shall without delay instruct their officers to carry out the measures set forth in the Board's directions and regulations dated July 21st, 1892, or such other measures as may be required to remove or abate the nuisance. This order is the outcome of a report by the inspecting officer of the Board in which slum property owned by the corporation themselves is dealt with. With one exception, the property is said to be damp, dirty, dark, overcrowded and badly ventilated, and it is recommended that these dwelling houses should be closed. The report recommends in addition that the sanitary inspector should be provided with a sufficient staff, that the medical officer's department should be reorganised and the medical officer should not engage in private practice, and that the milkshops lodging houses and bakehouses should be examined and their owners made to comply with the existing rules and regulations. The Board have pointed out to the local authority that there appears to be an unusually large proportion of insanitary property in the burgh, that in the opinion of those best able to judge there was a probability of cholera assuming an epidemic form in spring, and that therefore it was of prime importance that the local authority of the seaport in most direct communication with continental seaports should be thoroughly prepared to cope with the disease should it unfortunately appear in this country, and it is with these objects in view they have issued the order referred to.

February 14th.

IRELAND

(FROM OUR OWN CORRESPONDENT)

Dublin Hospital Sunday Fund

THE nineteenth annual meeting of the supporters of this Fund was held last week. The total contributions last year amounted to £4262 10s 5d, being an increase of £279 11s as compared with the previous year. The working expenses came to £260 8s 7d, or 6 46 per cent on the total collected. The committee, having ascertained that a sum of £4185 was available for distribution and for current expenses during the year 1893, determined to distribute the sum of £4020 among the sixteen participating institutions in consideration of subscriptions received and work done.

Dublin Main Drainage Bill

A meeting of burgesses of the City of Dublin was held last week at the Mansion House for the purpose of authorising the Corporation and burgesses to raise further moneys by borrowing to carry out the proposed main drainage scheme, and to lay a second line of pipes from the Varty works to Stullorgan, where the reservoirs are, so as to ensure an uninterrupted supply of water to the city and townships. The necessity for the main drainage scheme goes without saying and as regards the second line of pipes to the reservoirs, it is urgently wanted, as the line of pipes laid down twenty five years ago have become narrowed by the deposits from the Varty, which has seriously reduced the waterway of the pipes and materially diminished the volume of water sent from the Varty to the Stullorgan reservoirs. The effect of this is that one of the reservoirs is completely empty and the other less than half full. When the second line of pipes is completed it will be possible to thoroughly cleanse and overhaul the original pipes, and then, with a double or alternative service,

their training? 14 What payment should they receive during the period of their training? 15 What outlay in general would be required for organising such courses of training? 16 What payment should the trained members receive?

The first ten of these questions were discussed in committee, the last six, relating to the sanitary service, were discussed at the third general meeting of the Conference. Representatives of the governments of Orel; Radow, Yaroslav, Simbirsk, Kursk, Samara and Bessarabia recounted their experiences in their respective districts in the training of Sisters of Mercy and disinfection. They were unanimous in testifying to the value of even the shortest period of training. The period varied from ten days to six weeks, and the instruction was in all cases as practical as possible. The candidates received a short course of lectures on the rudiments of anatomy and physiology, and on the general principles of hygiene, nursing and disinfection, and at the same time were in attendance for so many hours each day on the patients in the infectious wards of the hospitals. When the epidemic reached any district there was almost everywhere a temporary reign of panic and disorder, the ordinary hospital accommodation and the sanitary and medical services proved inadequate to deal with the immense number of cases. Then the value of the temporarily trained Sisters of Mercy and of disinfectors was evident. As they were distributed in the villages the panic subsided and the peasants willingly accepted their services. Professor Pavlovski considered that in nursing cholera patients—where constant attention is necessary—women are preferable to male attendants, and many other speakers supported this view. The difficulty of providing medical men and nurses for distant villages was pointed out, and in illustration of this may be quoted the Samara government. Here in one uyezd alone there are 300 villages, separated from each other by an average distance of from thirty to forty versts. Many of these villages were unprovided with hospitals, doctors or even feldschars. The difficulty was, however, met to a great extent, and from the town of Samara from 180 to 200 trained attendants were distributed over the infected villages, where their services were greatly appreciated by the peasants.

In this work of training attendants and disinfectors the Red Cross Society has played the most active part. This Society, founded just twenty five years ago, has branches in nearly every part of the country. The payment of the Sisters of Mercy and disinfectors was derived from its funds. The scale of payment has varied considerably. Sisters of Mercy received from 15 to 50 roubles per month, the higher figure having been paid in the Yaroslav government, where the inhabitants charged them extortionate prices for food and other articles supplied to them. The disinfectors received from 10 to 15 roubles per month.

At the third general meeting of the Conference the following telegram of congratulation was sent to M Pasteur on the occasion of his seventieth birthday: "The Conference of Russian physicians who have taken an immediate part in the struggle with the cholera epidemic, and who are met in St. Petersburg from all the ends of Russia, congratulates the illustrious teacher on his seventieth birthday, wishing him many long years of activity devoted to the glory of his beautiful country, to the glory of science of which he is the pride, and of humanity which owes him so much."

MANCHESTER

(FROM OUR OWN CORRESPONDENT.)

Ancoats Healthy Homes Society

THE usual monthly meeting of this useful Society was held last week, Mr Phythian, a member of the City Council, having undertaken to entertain the poor people of Ancoats with a lecture on "Italian Towns in the Middle Ages." The large hall at New Islington was as usual crowded, the audience numbering about 600 all of whom were members of the labouring class. Mr Phythian, in the course of his lecture, showed pictures of Venice, Florence, Genoa, Pisa and other Italian cities, and spoke about their government, trades, arts and industries, and their relation to each other. He remarked that our own English towns were better in some respects than the foreign cities he had been describing, they were healthier and more convenient, but still they were very far indeed from being healthy enough,

and they were dismal and very ugly. He, however, expressed the opinion that Manchester might readily be very much improved if the people themselves would only take an interest in these things and communicate their wishes to their representatives on the city council.

Public Vaccination by Sanitary Authorities

At the 1st meeting of the Stretford Local Board the medical officer of health reported the occurrence of a case of small pox in a populous part of the township, and detailed the steps which had been taken by his advice to prevent further spread of the disease. A member of the board drew attention to the fact that the Moss side Local Board had recently appointed their medical officer of health as a temporary public vaccinator, and had issued advertisements to the effect that vaccinations would be performed by him at the expense of the Board. On its being suggested that the Stretford Board should take similar action for the purpose of securing the vaccination of the inhabitants of that district, a medical member of the board, who is also the Public Vaccinator, explained that such a course of action would be illegal, and that any moneys expended by the board on vaccination, would probably be surcharged by the auditor, as the guardians of the poor were the sole authority under the Vaccination Acts, and it would be undesirable to interfere with their functions, especially in face of a possible epidemic of small pox. Eventually the board decided to leave the matter in the hands of the Guardians.

The Small-pox Epidemic

Unfortunately there are, as yet, no good grounds for believing that the epidemic of small pox, which for some time past has prevailed in and around Manchester, has reached its worst. Although from the returns of the medical officer of health for the city the number of cases reported last week were fewer by twelve than in the week immediately preceding, nevertheless the distribution of the disease over the city area continues to be very wide, and there scarcely seems to be a district of the city which is quite free from infection. I also learn from the same source the sad fact that as time advances the type of the disease becomes progressively more serious, a dozen deaths from small pox having occurred in Manchester during the last fortnight. Several hæmorrhagic cases have occurred, which have of course proved fatal, and a large proportion of the cases admitted recently have been of the confluent or semi confluent variety. The small pox sheds at Monsall are still fully occupied, although they are much less crowded now than they were a fortnight since, for within the last few days an additional pavilion for twenty four beds has been opened, and fifty of the convalescent patients have been transferred to the "home" at Clayton Vale, which the corporation have recently adapted for the reception of overflow cases from Monsall. The Salford authorities, too, have bestowed themselves to provide hospital accommodation for smallpox cases within their own area instead of sending them to Monsall. Within the last few days smallpox has again broken out in Failsworth, the extra municipal district, where it will be remembered the first cases occurred, which remaining unreported led to the first importation of the disease into Manchester. Happily Failsworth has now adopted the Compulsory Notification Act, so that the local medical officer of health receives prompt intimation of the cases as they occur, and as the Monsall authorities still continue to receive any cases that occur in that district it is hoped that this second outbreak has already been satisfactorily dealt with.

The Withington Hospital Site

The appeal by the Withington Local Board from the decision of Mr Justice Chitty has been dismissed with costs by the Lords Justices, before whom the case was heard, and the Withington Local Board have intimated that, in face of that decision, they do not feel justified in carrying their appeal to a higher court. So far, therefore, as the Board is concerned, the Corporation of Manchester are now authorised to complete their hospital already partially erected on their own land at Withington. It appears however, that two private individuals have now brought an action at common law against the Corporation to restrain them from committing a nuisance. The action will be heard before Mr Justice Chitty this week, and until his decision is given the Corporation will perhaps scarcely feel themselves justified in proceeding to occupy their new hospital.

February 14th.

a hot one, which was then treated surgically like a common phlegmon. Healing took place very rapidly. More than 240 cases have been treated until now by this method by Moseing. Teucin has also been used in cases of fungous adenitis instead of *curettement* and has proved very successful. The injections showed a highly absorbent effect when made in the neighbourhood of swollen lymph glands. Beneficial effects of teucin injections have also been found by Dr Eliegi (Moseing's assistant) in cases of actinomycosis and lupus. Moseing believes that the injections of teucin will prove to be very useful, especially in cases of local tuberculosis of the soft tissues as caseous infiltrations are destroyed after the injections by the acute inflammation which follows, while more recent tuberculous infiltrations may disappear by being absorbed under the influence of the hyperemia caused by the injection.

February 15th.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND—

The following gentlemen having passed the necessary examinations and having conformed to the by laws and regulations, have been admitted Members of the College under the old regulations—

Barball Charles Edward, L.R.C.P. Lond., Kensington.
Broadhurst, Charles Henson, L.R.C.P. Lond., Anerley.
Carter John George, L.R.C.P. Lond., New Kent road.
Chamberlain, Edward Beatty, L.S.A., Broadthampton.
Christie Wm Ledingham, M.D. N. / Dundee & A. Zealand.
Darabseth, Naoraj Beramji, M.B. Aberd., Amp'hill square.
Edge Arthur James, L.R.C.P. Lond., St. Bartholomew's Hospital.
Morgan, Charles Arthur, L.S.A., Weston super Mare.
Plumbe Arthur, L.R.C.P. Lond., Newark street.
Sart, Frederick William Arthur, L.S.A., Haslingden.
Turner Philip Watson, L.R.C.P. Lond., Arlington road.

UNIVERSITY OF LONDON.—The following candidates have passed the Intermediate Examination in Medicine

ENTIRE EXAMINATION

First Division.—Guy Joseph Branson, B.A. Mason College Archer Wm. B. Cochrane, St. Bartholomew's Hospital Ralph Hopkin, Yorkshire College.
Second Division.—Percy Edward Adams, Percy Crompe Barford, Frank Marsden Burnell, J. F. Goodfellow Calverley, Cras Sempill De Segundo, William Edward Nickolls Dunn, and Thor' Hampton, St. Bartholomew's Hospital, Jackson Arthur Atkinson and Francis Chown, St. Mary's Hospital, Cecil Banting, Francis James Conitts, Alfred Henry Gerrard, Wm. Ernest Leethem Horn r and Arthur Marriott, University College, Jos ph Cohen, Hugh Mabinson Bigby and Richard Hamilton Townsend, London Hospital, Ernest Coleman, Guy's Hospital, Arthur Pollard Cummings, Yorkshire College, Robert Hughes, St. Thomas's Hospital, Tom Harold Hunt, Owens and Yorkshire Colleges, Frank Harwood Jacob and Fredk. Septimus Percy Kings College, William Percy Nicol, Mason College, George Basil Price, Bristol Medical School and Clifton Laboratory, Matthew Harper, M. d'iesex Hospital, Sydney Gordon Tippet and Francis Kenneth Wilson, Westminster Hospital, Thomas Henry Wells, Middlesex Hospital and Birkbeck Institute.

EXCLUDING PHYSIOLOGY

First Division.—Eustace Bernard Bostock, Mason College, Arthur William Jenkins, University College.
Second Division.—Wilfrid Allport, Charles Holt Caldwell and David Horwich, Mason College, Maxwell Dick, Robert Macfie Johnston, Edward Thomas Jones and Morris Wilks, University College, Arthur David Ducat, St. Bartholomew's Hospital, William Henry Holliday and Albert Edward Hutton, Yorkshire College, Clarence Harry Mott, London Hospital.

PHYSIOLOGY ONLY

First Division.—Arthur Hannard, University College.
Second Division.—Joseph Norwood Brown, George Wilfrid Costling, Austin Edward Reynolds and Sidney Edward Shoppee, University College, John Samuel Chater, St. Bartholomew's Hospital, Matthew Leslie G. Halliart, Mason College, George Robert Harcourt, St. Thomas's Hospital, Frank Drew Harris and Sydney Price, James, St. Mary's Hospital, Amelia Maitland Le Pelley, London School of Medicine for Women, John Vace and Archibald Tait, Yorkshire College, William Matthews Price, Guy's Hospital, Robert Henry Tompsett, St. Thomas's Hospital, Archibald Young, Sheffield Medical School and University College.

UNIVERSITY OF DUBLIN.—The following degrees were conferred by the University Cypat this week—

Bachelor in Medicine, Surgery and Obstetrics.—Andrew Francis Dixon, William George Danwoody, Hampton Atkinson, Gray John George, Hearn Hugh Irwin, Henry Thomas Knapp, Francis Hyde Maberly, Edward Hugh Montgomery, Daniel Frederic Ramsay, and Richard A. Skekelton.

Doctor in Medicine.—Arthur Auld Ali, Charles Robert Frowne, Daniel Frederic Hambro, Wm. Ribton Spowart, Charles Eltring, in Stokes Philip Cramp on Walker and Digby Cooke Whit e.

THE WOODSTOCK HOSPITAL, CAPE TOWN.—On the 16th ult. the suburban hospital, situated in Woodstock, Cape Town, was opened by the Governor Sir Henry Loch, with masonic honours and amidst great enthusiasm. The cost of the hospital is estimated to amount to about £1500, which has already been nearly covered by subscriptions.

THE OPIUM TRAFFIC.—On Wednesday last a meeting was convened at Exeter Hall, under the presidency of Sir Joseph Pease, M.P., to protest against the opium traffic. Resolutions urging reasons against the continuance of the traffic and calling upon Her Majesty's Ministers to suppress it, in the interest alike of humanity in general and of the people of India in particular, were carried unanimously.

THE SANITARY INSPECTORS ASSOCIATION.—Dr B. W. Richardson, the president of the above Association, presided at the annual dinner, which was held in London, at the Criterion on Saturday, Feb. 11th. In replying to the toast of his health, Dr Richardson spoke of the genuine tribute which had been paid to the Society by French scientific men and referred to the awakened interest in England. It was the mission of the Association, he said, to make the nation a garden of purity and sweetness.

FOOTBALL CASUALTIES.—In a match on the new Recreation Ground at Alton, Surrey, on the 4th instant between Farnham and Alton, a player fractured his jaw. On Saturday last the following accidents occurred. During the progress of a match between the Leeds Parish Church and Sunderland teams at Crown Point a player of the former team sustained serious internal injuries and was removed to the infirmary during a match at Wall-end-on Tyne between Percy Park and Wallsend a member of the latter team fractured his leg below the knee, whilst playing in a League game at Darwen a player fractured one of his legs.

CHARING-CROSS HOSPITAL.—The report of the annual Court of Governors which was held on the 15th inst was from a financial point of view, far from satisfactory. Indeed the state of things in this respect, the report stated, afforded ground for considerable apprehension so that unless help be vouchsafed to a large extent the number of beds in the institution will have to be speedily reduced. The ordinary income accruing to the general fund during the past year had amounted to £8566, of which £1790 was derived from donations against £3815 from the same source in 1891. It is to be hoped, as the chairman remarked, that the operations of the charity may not be crippled by want of means and that projects for enlarging the accommodation for both students and nurses may yet be carried out.

METROPOLITAN ASYLUMS BOARD.—The number of patients remaining in the several fever hospitals of the Board at midnight on Feb. 14th was as follows—Eastern Hospital, 193 scarlet fever, 59 diphtheria and 34 enteric fever, North Eastern Hospital, 493 scarlet fever, North Western Hospital, 204 scarlet fever, 96 diphtheria and 7 enteric fever, Western Hospital, 212 scarlet fever, 32 diphtheria and 9 enteric fever, South Western Hospital, 238 scarlet fever, 53 diphtheria and 23 enteric fever, South Eastern Hospital, 289 scarlet fever, 13 diphtheria, 25 typhus fever and 13 enteric fever, Northern Hospital, 525 scarlet fever and 14 diphtheria, Gore Farm Hospital, 300 scarlet fever. On the same date on the hospital ship *Atlas* and *Catalina* there were 46 and 71 cases of small pox respectively.

SOCIETY OF PUBLIC ANALYSTS.—A special meeting of the members of this Society was held on Wednesday last at the rooms of the Chemical Society with a view to the consideration of a series of resolutions bearing upon the working of the adulteration laws. The chairman Mr M. A. Adams, F.R.C.S., said the Council of the Society had invited a number of representative men to attend the meeting. He then proceeded to move resolutions to the effect that an amendment of the adulteration laws was urgently required and that it is necessary that adequate provision be made for securing uniformity in their application further that it is desirable that there should be a duly constituted chemical department attached to the Local Government Board and that the compulsory combination of the two offices of medical officer of health and public analyst is undesirable. The resolutions were carried.

an uninterrupted supply of water to the city will be practically assured. A Bill will be promoted by the corporation for the purpose of borrowing £100,000 to carry out the necessary works, and as the Bill had the support of the late Government and also of the present Chief Secretary and the Local Government Board, it is not probable that it will be opposed at any stage.

Cork District Lunatic Asylum

During the past year 277 patients were admitted to the asylum, and the daily average number resident was 1076. The total number under treatment was 35 more than in 1891, 103 of the inmates were discharged recovered, 70 improved, 5 not improved and 68 died. The resident medical superintendent refers in his annual report to the great increase in lunacy which has taken place in the county as contrasted with twenty five years since, although the population has diminished. That lunatics are now more frequently sent to asylums for treatment partly accounts for this increase. Formerly they were only sent in when too dangerous to be at large and in many cases when all hope of recovery had gone. The deaths came to 68, which shows a mortality of 6.3 per cent. on the daily average number resident, and is the lowest on the records of the asylum. Save one case of mild typhoid fever there was no zymotic disease. The new building begun nearly three years since is now approaching completion, and it is probable that it will be available for occupation some time during the present year. It has been constructed to accommodate 420 patients, and this, with the provision in the main building and hospital, will give a total accommodation for about 1320. The numbers in the asylum, on the day the report was presented, were 1100, so that it will not be difficult to fill the vacant beds if care is not taken to keep out chronic and incurable patients. The new building consists mainly of large day rooms and dormitories, and has been constructed for the accommodation of quiet patients, three of the male wards in the main building will be given over to the female patients, and only 200 beds will be retained for the men, for the treatment of recent suicidal, epileptic and dangerous cases. The other works, such as the reconstruction of the laundry, the erection of sanitary turrets on the male and female sides of the main building and a mortuary, will be commenced this spring. The total expenditure was £22,120 16s 8d, or £20 11s 1d per head, this being 15s 4d per head less than in 1891.

Nile street Hospital, Cork.

The annual ball for the benefit of the lying in hospital, Nile street, was held last week. The ball was well attended and a very considerable sum has been obtained for a deserving charity.

Mr Werner has been appointed Lecturer on Ophthalmology in the Catholic University Medical School.

February 14th.

BERLIN

(FROM OUR OWN CORRESPONDENT)

The Twelfth Congress for Internal Medicine

The twelfth Congress for Internal Medicine will meet at Wiesbaden from April 12th to 15th. Immermann of Biele in the chair. On the 12th Rumpf of Hamburg and Gaffky of Giessen will speak on cholera. On the 14th the subject of "traumatic neuroses" will be dealt with by Strümpell of Erlangen and Wernicke of Breslau. The following papers are also announced: Ziemssen of Munich on Parenchymatous Injections in Diseases of the Tonsils, Emmerich of Munich on the Preparation Preservation and Application of "Immunotoxinprotein" for the Cure of Infectious Diseases and Protective Inoculation against them, Adamkiewicz of Cracow on Cancer and its Treatment, Jaksch of Prague on the Chemistry of the Blood, Meringe of Halle on the Function of the Stomach.

The German Pestilence Act

The draught of an Act concerning the combating of diseases dangerous to the public was laid before the Federal Council of the German Empire a few days ago. It is in six sections consisting of forty six paragraphs. The first section treats of notification, the second of the ascertaining of the disease, the third of protective measures, the fourth of indemnifications, the fifth consists of general regulations and the sixth deals with penalties. It is hoped that the Act will pass through the various legislative stages and come into force this year.

An International Cholera Conference

It is stated in the papers that an International Cholera Conference will meet in Dresden this month, but I hear on excellent authority that it will not meet till March. The *Politische Korrespondenz* (*Political Correspondence*) writes: "The measures which were taken by the various Governments last autumn on the occasion of the outbreak of cholera had an extremely paralysing effect on all commercial traffic. The possibility of cholera breaking out again next spring has given rise to the general wish to bring about an international discussion of the questions at issue, with a view to taking care by joint agreements that, on the one hand, the spread of the pestilence be combated in the most uniform manner possible, and that, on the other, the limitations of traffic caused thereby do not go beyond the limits of scientifically recognised necessity. The Austrian Government has therefore suggested to the other European States the convening of an international conference to deliberate the above questions. It is also intended that the question of river navigation shall be discussed, and an agreement regarding the questions connected with quarantine, in the spirit of the resolutions arrived at by the Venice Conference last year aimed at. We learn that this suggestion has been favourably received by all the Governments, and that such an international conference is expected to meet in Dresden in the end of February." The *Berlin Post*, a paper likely to be well informed on such a point, states that the suggestion was not made by Austria-Hungary alone, but by that State and Germany conjointly.

Professor Dubois Reymond

Professor Dubois Reymond last Saturday celebrated the fiftieth anniversary of his graduation.

February 18th.

VIENNA.

(FROM OUR OWN CORRESPONDENT)

Infectious Diseases in Austria-Hungary

WHILE no case of cholera has occurred in the Austrian part of the empire during the last week, the occurrence of single cases has been notified again at Budapest, where five cases are now under treatment at the cholera hospital. An outbreak of influenza has been reported from some villages in Styria, where the mortality has been considerably increased by that disease. At Vienna some cases of intestinal influenza have been observed.

Teucrin in Chronic Inflammations

Ever since Professor Liebreich of Berlin showed that the cantharidine compounds produce similar effects to Koch's tuberculin, various experimenters have searched for substances acting in the same manner, and there are certainly a great number of different chemical bodies which, when administered by injection into the animal organism, produce local hyperemia around the remains of chronic inflammatory processes and the site of foreign bodies, as well as an increase of the production of lymph accompanied by so-called general symptoms—e.g., tachycardia, fever &c. Such a "lymphagogue," as it may be called from the experiments made by Professor Heidenhain of Breslau, has now been found by Professor Mosetig of Vienna to exist in the plant called *Teucrium scordium*, one of the Labiate which was officinal many years ago and which was known even to Dioscorides as possessing an antiseptic action. Mosetig used an aqueous extract prepared from the herb which he called teucrin the dose varying up to five grammes. When injected subcutaneously in healthy or sick persons teucrin produces a sudden rise of temperature, reaching 38.5° to 40.0° after four hours and lasting from eight to ten hours. The fever thus produced exhibits the characters of Volkmann's aseptic fever, the patients feel themselves as well as before, the appetite is increased, and the secretions and excretions are not changed. Locally there is only a slight swelling round the puncture, sometimes oedema and pain are produced persisting for twenty four hours in healthy persons, but in diseased tissue a very active hyperemia is induced lasting some days and its effects manifest themselves by changes in the morbid tissue, and even finally, by the total absorption of the latter. Teucrin injections were employed by Mosetig in cases of cold tuberculous abscesses. Generally three grammes of the teucrin were injected near the abscess subcutaneously. Two days after the injection the cold abscess had become

Appointments.

Successful applicants for Vacancies Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET Office directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number

AILEY WM. M.D. M.S. Irel. has been appointed Medical Officer for the Third (Eastern) Sanitary District of the Hexham Union, vice Richards deceased.

BEAUMONT, E. L.R.C.P. Lond., M.R.C.S. has been appointed Assistant Medical Officer pro tem to the Lewisham Board of Guardians.

BROWNING, G. M.R.C.S. has been reappointed Medical Officer of Health for the Stocksbridge Urban Sanitary District of the Wortley Union.

COOPER, JAMES, M.R.C.S. L.R.C.P. Lond. has been appointed House Surgeon to the Great Northern Central Hospital Holloway road.

DAVIES, H. M.R.C.S. has been reappointed Medical Officer for the Cottage Homes of the Pont y Pridd Union.

EVATT, E.P. L.R.C.P. L.R.C.S. Edin. has been reappointed Medical Officer for the Tenth Sanitary District of the Hexham Union.

FERNY, M.D. Edin. M.R.C.P. Lond. has been appointed Honorary Physician to the Essex and Colchester General Hospital.

FERNIE, F.E. M.R.C.S. L.R.C.P. Lond., has been appointed Junior House Surgeon to the Stockport Infirmary.

HILLMAN G.B. L.S.A. has been appointed Medical Officer of Whitwood vice McMaster.

HITCHINS, C.V. M.R.C.S. has been appointed Medical Officer of Health for Weston-super-Mare.

HOGG, R.B. M.R.C.S. has been appointed Senior House Surgeon to the Darnley Hospital New Zealand.

KEMPE, C.M. M.R.C.S. has been reappointed Medical Officer of Health for the Shoreham Port Sanitary Authority.

KEMMIS H.M. L.R.C.P. Irel. M.R.C.S. has been appointed Medical Officer for the No 1 Sanitary District of the Bridgwater Union.

MINLEY, J. HERBERT H.M.B.C. Camb. M.R.C.S. D.P.H. Camb. has been reappointed Medical Officer of Health for the County Borough West Bromwich.

PITCHAM, G.K. M.B. C.M. has been reappointed Medical Officer of Health, Littleborough.

REICHAERT, E.N. M.B. Lond., has been appointed Medical Officer for the Ewell, Chessington and Cuddington Sanitary Districts of the Epsom Union.

THOMSON, ARTHUR, M.B. Edin. D.P.H. Camb. has been appointed Medical Officer of Health to the Urban Sanitary District of Stratford-on-Avon, and to the Rural Sanitary District of Stratford-on-Avon.

TREWEY, LULIAN L.R.C.P. L.R.C.S. Edin. L.F.P.S. Glasg. has been appointed Senior House Surgeon, Lady Dufferin's Hospital at Agra, India.

VACHER, F. F.R.C.S. M.R.C.P. Edin. has been appointed Medical Officer of Health for the County Cheshire.

VINEACE, J.H. M.B. Lond. M.R.C.P. has been appointed a Physician to St. John's Hospital for Diseases of the Skin.

WOODFORD, W.T.G. M.D. Lond. has been reappointed Medical Officer of Health for the Berkshire Combined Sanitary Districts.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

CANCER HOSPITAL (FREE) Fulham road S.W.—House Surgeon for six months. Salary at the rate of £50 per annum with board and residence.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST Victoria park E.—House Physician for six months. Board and residence, and allowance for washing provided. (Apply to the Secretary 24, Finsbury circus, E.C.)

COUNTY ASYLUM, Prestwich Manchester.—Junior Assistant Medical Officer (unmarried). Salary commences at £100 per annum with prospects of future increases.

GENERAL HOSPITAL, Birmingham.—House Physician for one year. Salary £70 per annum, with residence board and washing.

LONDON LOCK HOSPITAL, Harrow road W.—House Surgeon to the Female Hospital. Salary £100 per annum, with board, lodging and washing.

LONDON TEMPERANCE HOSPITAL, Hampstead road N.W.—House Surgeon for six months. Salary at the rate of 60 guineas per annum with residence in the hospital, board and washing provided, and an honorarium of five guineas conditionally.

LONDON TEMPERANCE HOSPITAL, Hampstead road N.W.—Junior House Surgeon for six months.

METROPOLITAN ASYLUM BOARD.—First Assistant Medical Officer for the Leavenden Asylum for Imbeciles near Watford Herts. Salary £100, rising £20 annually to £200 with board, furnished apartments and washing (Apply at the Chief Offices, Norfolk street, Strand, W.C.)

NOTTINGHAM GENERAL DISPENSARY.—Assistant Resident Surgeon. Salary £150 per annum with rooms and attendance.

OLDHAM INFIRMARY.—Senior House Surgeon. Salary £50 per annum with board, lodging and washing.

OLDHAM INFIRMARY.—Junior House Surgeon. Salary £50 per annum with board, lodging and washing.

PUBLIC DISPENSARY, 39 Stanhope-street, Clare market.—Physician. (Apply to the Secretary 14 Portugal street Lincoln's-inn.)

ROYAL SOUTH LONDON DISPENSARY, St. George's-cross, S.E.—Honorary Surgeon.

SALFORD ROYAL HOSPITAL.—House Surgeon. Salary £100 per annum, with board and residence.

ST JOHN'S HOSPITAL FOR DISEASES OF THE SKIN Leicester square, W.C.—Assistant Physician.

ST JOHN'S-WOOD AND PORTLAND TOWN PROVIDENT DISPENSARY, N.W.—Third Medical Officer. (Apply to the Secretary, 1, Henstridge-villas, St. John's-wood.)

ST. MARY'S HOSPITAL MEDICAL SCHOOL, London.—Demonstratorship in Chemistry and Physics. Salary £100 per annum.

ST PANCRA'S AND NORTHERN DISPENSARY, 120 Euston road.—Physician Accoucheur. (Apply to Hon. Sec., 23, Gordon street, Gordon square W.C.)

THE HOSPITAL FOR SICK CHILDREN, Great Ormond-street, Bloomsbury W.C.—Surgeon.

THE HOSPITAL FOR SICK CHILDREN Great Ormond street, Bloomsbury W.C.—Assistant Surgeon.

UNIVERSITY OF GLASGOW.—Four Examinerships for Degrees in Medicine. Annual fee in each case is £30 and the term of office is till Dec. 31st, 1896.

WEST RIDING ASYLUM Wakefield.—Resident Clinical Assistant, for six months. Board and furnished apartments provided.

YORK DISPENSARY.—Resident Medical Officer. Salary £150 a year with furnished apartments, coals and gas.

Births, Marriages and Deaths.

BIRTHS

BARKER.—On Feb 7th, at Harley street, Cavendish square, W, the wife of Arthur E. Barker F.R.C.S. of a daughter.

DALLEWY.—On Feb 10th, at the Crescent, Wem Shropshire, the wife of John Dallewy L.R.C.P. M.R.C.S. of a daughter.

KENNEDY CASLEY.—On Feb. 6th at the Old House Ipswich, the wife of R. Kennedy Casley, M.D. of a daughter.

LODGE.—On Feb. 10th, at Raglan, Monmouthshire, the wife of A. G. S. Lodge M.B. of a daughter.

PESKETT.—On Feb 10th, at York House, Burnham, Somerset, the wife of A. W. Chalmers Peskett, M.A., M.B., B.C. Cantab. of a daughter.

WALKER.—On Feb 14th, at Pine House, Hurworth-on Tees Darlington the wife of Dr C. E. Walker of a son.

WILSON.—On the 9th inst. at Denham House Goldhawk road, London W. the wife of James Wilson M.D., of a daughter.

MARRIAGES

JACK-BARROW.—On Feb 14th at St. Mary's The Boltons South Kensington Dr Jack, of Harley gardens to Matilda Stewart, third daughter of the late William Donovan Barron, of Gloucester place Portman-square.

MACGREGOR-KAYE.—On Feb. 8th, at All Saints' Cawthorne by the Rev C. T. Pratt, M.A. Vicar assisted by the Rev John Kaye, M.A. of Westbury Wilts, brother of the bride Alastair MacGregor, M.B. Edin & C.M. of Shepley Yorks., youngest son of the late Rev. Alexander MacGregor, M.A. West Church, Inverness to Annie only daughter of Joshua Kaye Esq., of Dean Hill, Barnsley Yorks.

NASH.—WILSON.—On Feb 9th at St. Andrew's Church Plymouth, by the Rev W. Gray Rector of Meavy Walter Gifford Nash F.R.C.S. Eng., son of the Rev F. Gifford Nash, Vicar of Clavering Essex to Catharine Isabel Moore Wilson, daughter of J. Walker Wilson Esq. 10 Leigham Villas Plymouth.

RICHARDSON-EGGLAND.—On Feb 1st at St. Stephen's Church, Kir stall Leeds by the Rev Canon Talbot assisted by the Rev N. Egerton Leigh, Vicar of Kirtall, Rev Cecil Sykes Vicar of Cowick and the Rev J. Cockerill, Burley Martin James Richard son, M.B. youngest son of Martin Richardson Esq., solicitor Bridlington to Elizabeth Maud, youngest daughter of N. H. Egland Esq. M.D. St. Ann's Lodge Barley Leeds.

ROOKE-COCHRAN.—On Feb 2nd at St. Margaret's Church Westminster Ernest Morley Rooke M.R.C.S. Eng. L.R.C.P. Lond., son of Thomas Morley Rooke M.D. Cheltenham, to Fanny Josephine second daughter of James Cochran formerly of Widgeia Estate Riverina New South Wales Australia.

WHITEHEAD-CATLEY.—On Feb 13th at St. Mark's Woolston Hants, Surgeon Captain H. R. Whitehead, Army Medical Staff second son of the late Rev T. G. Whitehead, M.A., to Evelyn Wynne, second daughter of Henry Cayley, Esq., of the Towers Woolston.

DEATHS

DANIEL.—On Jan 25th at Wareham Dorsetshire Woodruffe Daniel, M.F.C.S. Eng.

DAVIES.—On Feb 7th, at Marlborough buildings, Bath William Davies, M.D., F.R.C.P.L. aged 74.

HARRIS.—On Dec 22nd 1892, at Barkley West, South Africa William Ross Harris, J.P. M.R.C.S. L.R.C.P. District Surgeon aged 33, second son of the late George Harris J.P., Tredegar, Mon.

HUTTON.—On Feb. 13th, at Carshalton Stapleton hall road, Stroud green N. Robert James Hutton Surgeon suddenly.

MARSHALL.—On Feb 4th at his residence Wallingford J. H. Marshall, M.R.C.S. aged 52.

WAGHORN.—On Feb. 10th, at Newport Surgeon Lieutenant-Colonel Henry Waghorn late Army Medical Staff aged 55.

WALFORD.—On Feb 9th, at Uppingham, Augustus David Ceely Walford M.R.C.S. L.S.A., aged 71 years.

N.B.—A fee of 6s. is charged for the insertion of Notices of Births, Marriages and Deaths.

PRESENTATION—On Tuesday, Feb 7th, Dr Fletcher Beach was presented by the officers, attendants and nurses of Darenth Asylum for Imbecile Children with a pair of handsome silver candelabra on his resigning the post of medical superintendent after eighteen years' service. He is succeeded by Dr Walmsley, late senior assistant medical officer of Leavesden Asylum.

LITERARY INTELLIGENCE—If wisdom fails to penetrate the civic understanding it will assuredly not be because of the absence of a multitude of counsellors. The cry is still they come. The radiance from a new guiding star is on the horizon—nay, it has verily risen. The first number of *London a Journal of Civic and Social Progress*, is already published. If the new journal carries out its programme and is successful in instilling its principles it will have accomplished a notable work.

LONDON FEVER HOSPITAL, LIVERPOOL-ROAD—At the annual meeting of this institution, held on Friday, Feb 10th, it was stated in the report that during the year 1892 there were 748 patients admitted into the hospital. The mortality was 1.9 per cent. The donations and subscriptions showed an increase of £1097 over that of 1891. Lord Balfour of Burleigh, who presided, said the cost of the year's work had been £9644, of which the patients had contributed £2692. An appeal was made for subscriptions to defray an estimated sum of £6000 required to provide further accommodation for the nurses.

PROVIDENT SURGICAL APPLIANCE SOCIETY—The twenty first annual dinner of this Society was held in London at the Hôtel Métropole on Monday, Feb 13th. Mr Arthur Stride, manager of the London, Tilbury and Southend Railway Company, who presided, directed attention to the way in which help was given by this Society. The Society gave help without regard to age, race or creed, it had no system of letters of introduction and it tried to give a maximum of aid with a minimum of trouble. During the past year it had relieved 6516 people. The subscriptions collected during the evening amounted to £1181.

ÆSCULAPIUS LODGE OF FREEMASONS, NO 2410—The ordinary meeting of this lodge was held at the Café Royal, Regent-street, on the 8th inst., when the W M (Deputy Inspector General Belgrave Ninnis, M D) presided, supported by the officers of the lodge and a number of brethren. After the minutes of the last meeting had been read and confirmed Bro Surgeon Captain R. Ashton Bostock, L R C P Lond, M R C S, was unanimously elected a joining member. Bro W Arbutnot Lane, M S Lond, F R C S Eng, was admitted to the third degree by the W M. The routine business of the lodge having been transacted and a number of letters of apology for non attendance on account of illness and professional duties on the part of absent members having been read by the secretary, the lodge was closed. The brethren afterwards dined together and spent a pleasant social evening, when the loyal and masonic toasts were duly honoured and suitably responded to.

NOTES IN PARLIAMENT

The Identification of Foreign Meat.

In addition to Mr George Lambert's Bill, to which reference was made last week, there is a measure on this subject presented for the acceptance of Parliament by Mr Coningsby Dismell. The two Bills are not unlike in their main features. They both provide for the labelling of the foreign meat and the distinguishing of shops where it is sold. Instead however, of making use of the local authority for purposes of registration, Mr Dismell proposes that all dealers in foreign or colonial meat shall take out a yearly licence from the Commissioners of Inland Revenue. He also invests Customs officers, medical officers of health, inspectors of nuisances and police constables with the powers of inspection authorised under the Sale of Food and Drugs Act of 1875, permitting them, however, to take samples of the meat without going through the form of purchase prescribed by that Act. Another point in Mr Dismell's Bill is that all foreign or colonial meat forwarded by public conveyance shall be labelled and consigned as such.

Pleuro-Pneumonia.

In anticipation of the debate next month on the subject of pleuro-pneumonia Dr Farquharson has given notice of an amendment to the

effect that any attempt to interfere permanently with the distribution of store cattle from abroad throughout the United Kingdom will seriously affect the interests of agriculture, more especially in Aberdeen shire, where cattle feeding is extensively and successfully carried on.

The Use of Hemp Drugs in India.

Mr Schwann, one of the representatives of Manchester, has given notice of the following motion for Friday, March 3rd, viz.—“That in the opinion of this House the growth, cultivation, and sale of bhang, ganja, charas and other preparations of hemp by the provincial governments of India produce much misery, poverty, insanity and moral deterioration among the people of India, and whereas similar results in Turkey, Egypt and Greece have led to the absolute prohibition in those countries of the manufacture and common sale of hemp drugs, it is desirable that the Secretary of State for India should order a commission of experts to inquire into and report upon the cultivation of, and trade in, all preparations of hemp drugs in Bengal, the effect of their consumption upon the people of that presidency, and the desirability of the prohibition of their sale, not less than one-half of such commission to be composed of non official natives of India.”

Sanitation in Schools.

In the House of Lords on the 10th inst. Lord Norton put a question as to the amount of school space required for sanitary purposes. Lord Kimberley explained that the object of the circular issued by the Vice President of the Council was to obtain precise information so that schools might be brought up gradually to a higher standard in respect of sanitary and other requirements. In the discussion which followed Lord Salisbury deprecated forcing upon school managers a new and costly system of arrangements of whatever kind.

Tuberculosis in Cattle.

In the House of Commons on the 10th inst. Mr Gardner, in reply to Mr Hozier, said he should be glad to take any steps which might be found to be practicable to minimize the extent to which tuberculosis prevails amongst cattle, but whilst the subject is engaging the attention of the Legislature it would be impossible to propose legislation of an expensive nature on the subject.

Irregular Death Certification.

In reference to an inquest recently reported, in which the certification of death was deferred for some days after the actual decease, Mr Asquith, in answer to a question put by Mr Maden, said the circumstances of the case were put before the Registrar General, who would no doubt take any proceedings which may be found to be necessary. Other irregularities, said the Home Secretary, would appear to have been disclosed in connexion with the case, and these would be reported to the Director of Public Prosecutions.

The Galway Hospital.

In answer to a question put by Mr Kenny respecting the amount of attendance at a hospital necessary to entitle a student of medicine to present himself for examination, Mr Morley stated that he had been officially informed that the Galway Hospital fulfils in every particular the requirements set forth in the regulations of the Royal University.

Ill-fed School Children.

Mr R. Wallace put a question on this subject, and elicited from Mr Acland a reply to the effect that from inquiries he had made he felt sure that a very large number of children attend school without having been supplied with a sufficient amount of food. He would, however, communicate with the managers of some of the largest schools in order to gain information on the matter.

The Poor Law Commission.

In the House of Commons on the 9th inst. Mr Fowler in reply to Mr Chamberlain and Mr Hozier said the system of Poor Law relief into which the Royal Commission is appointed to inquire is the system now in force in England and Wales, and to which alone the powers and duties of the Local Government Board extend. Scotland and Ireland have separate and different Poor Laws, with separate central authorities for their supervision.

Sanitary Authorities and Infectious Diseases.

Mr H. Fowler, in reply to Mr Johnson Ferguson, said he was unable to state the number of sanitary authorities who have made special provision for the accommodation of persons suffering from infectious diseases, but should be prepared to agree to a return on the subject if it be moved for.

Pleuro-pneumonia.

On the 14th inst. Mr Macartney asked the President of the Board of Agriculture if his attention had been called to a resolution passed at a meeting of the Royal Agricultural Society urging the slaughter of all foreign cattle landing in the United Kingdom at the port of debarkation. Mr Gardner said, though he had received a copy of that resolution he was unable to enter into any undertaking to introduce or support a measure to make such slaughter compulsory at the port of debarkation.

The Tuberculosis Commission.

In answer to a question by Mr Yerburgh Mr Gardner said frequent communication had been had with the Royal Commission with regard to the inclusion of tuberculosis in the Contagious Diseases (Animals) Act, and the Commission was extremely desirous to complete their work so far as is compatible with thorough scientific accuracy in respect of the questions committed to them.

Indian Opium.

Sir M J Stewart gave notice that on an early day he would move that a humble address be presented to Her Majesty to appoint a Royal Commission to inquire into the production, manufacture, and export of opium from India, and to move a resolution

direct it to be given in half ounce doses or just as he thinks proper. This mixture keeps good for some time and the patient can be placed under treatment without of necessity knowing that there is anything special about it as must be the case if portions of the gland either raw or partially cooked are given.—We have also received a letter from *Messrs Brady and Martin* of Newcastle-on-Tyne who describe the precautions they adopt to secure that the thyroids used are obtained from healthy animals and are themselves free from morbid changes. They do not agree with Dr Napier (Glasgow) as to the frequency with which "cysts" occur in the gland, which they place at about 2 per cent. In preparing the glands they are carefully sliced and examined, and if a "cyst" is found that lobe is rejected and the knife which has cut it is carefully cleaned and sterilised before it is used to cut another lobe. The lobes are then bruised in a mortar, and for each lobe there is added 1 c.c. of glycerine and 1 c.c. of a 0.5 per cent. of carbolic acid in boiled distilled water. The mixture is allowed to stand for twenty-four hours and squeezed through a cloth in a press to obtain as much liquid as possible. The product for each lobe was found by Dr George Murray in his first experiments to be about 8 c.c.

Mr John P. Henry—We have received several papers on the same subject as our correspondent's contribution, all of which, owing to the demands on our space, we are unable to publish in *extenso*. We propose, however, in an early issue to publish the important facts recorded by these contributors, together with such illustrations as may be required.

Mr William Muir—Our correspondent probably refers to a solution of nitrate of silver. The cloudiness it produces does not necessarily indicate animal matter however. It may be used to test the purity of distilled water, for almost all other waters contain chlorides.

Operator—We do not see that the cases are quite parallel or that medical men, as such, would be well suited for doing medical agency work.

ANCIENT MEDICAL BILL.

To the Editors of THE LANCET.

SIRS—Please insert the following copy of a portion of an apothecary's quarterly account for medicines supplied to Queen Elizabeth. The original is in Latin—

"*High Morgan, her Majesty's Apothecary asketh allowance for the medicines following—viz., for her Majesty's own person—from the 24th of June, 1588, being Mydsomer Day unto the 29th of September 1588, being Michaelmas Day, to be paid by the treasurer of her highness's Chamber. A confection made like a Mannus Christi (a tablet such is candied horehound is now made in) with bezar stone and unicorn's horn, by the Queen's order, for Mrs. Skipwith 11 shillings. A Royal sweetmeat with incised rhubarb by the Queen's order, for Mrs. Scudamore, 10 pence. Rose water for the King of Navarre's (afterwards Henry IV. of France) ambassador 12 pence. A conerve of barberries with preserved damascene plums and other things for Mr. Raleigh afterwards Sir Walter Raleigh, by the Queen's order 6 shillings. Sweet scent to be used at the christening of Sir Richard Knightly's son, 2 shillings and 6 pence."*

Gargles occur frequently and now and then hysteric and diuretic medicines. Articles of perfume are numerous especially *suffitus floriferi* and "*aqua rosarum*," which last seems to have been used abundantly in the Chapel Royal, chamber dressing room, supper room wardrobe, laundry and *pro domo* *Ridhercourt*." The amount appears by the receipt—

Received the 5th day of December 1583, of the Right Hon. Sir Thomas Heneage Knight Thre of her Majesty's chamber by force hereof lxxxij. s. vijs. viijd. [1583 7a. 8d.]

High Morgan Pharmacopoeus.

I am, Sirs yours faithfully

CHARLES WILLIAMS

Norwich, Feb 14th, 1893

THE SUNNY CORNERS OF HOMELAND

A COPY of a new Illustrated monthly venture with the above title, makes its appeal to our sympathies from our Library Table. There is no reason that we can see why such a publication as the one under notice should not occupy a place more or less useful in the series of periodical guide-books issued from time to time. We cannot say very much for the illustrations which are decidedly wanting in finish and pictorial effect. But the object aimed at—viz. to call increased attention to the attractions of our English health resorts as compared with those in foreign climes with their often in alabrious sanitary arrangements—cannot but have our commendation. The number contains a short article by Dr P. de Villiers on the advantages of Hastings as a temporary residence.

DENTISTRY IN FRANCE.

Alcedus asks—Can any of your readers inform me what facilities there are for studying dentistry in Paris or Montpellier or where definite information on the subject may be obtained?

A. F.—We are not aware of any suggested relationship between the two diseases named. All the larger text-books of medicine contain ample notice of them. For special details reference might be made to Dr Thib's work on Leprosy and to the Clinical Society's Report on Mischodema.

THE OFFICE OF CORONER.

AMONGST the questions of commanding interest in civilised and populous communities must be placed that of the complete and satisfactory method of ascertaining by judicial inquiry the cause of death in cases in which that event has been sudden or attended by circumstances of a suspicious character. Yet, important as it is the subject is one on which even in intelligent minds, much ignorance prevails. To diffuse information, therefore, on points in connexion with the working of the coroner's court has been the laudable object of Mr F. W. Lowndes M.R.C.S., by the publication of a pamphlet entitled "*Reasons why the Office of Coroner should be held by a Member of the Medical Profession.*" The arguments adduced in support of the contention suggested by the title are sustained by reference to the history of cases which at the time obtained world-wide celebrity. The brochure is deserving of a large circulation.

Messrs. Mauston, Sican and Weddel.—Fugenol acetamide does not, as far as we can learn, appear to be obtainable in London. The original notice of its action appeared in a German pharmaceutical journal, so that probably a German firm of chemists might be able to obtain it.

Mr William Robinson.—We cannot concur in the advice given to our correspondent's friend. He and his friends must contrive some more creditable way of finding the means to complete his medical studies.

LEGAL RESPONSIBILITY FOR ILLNESS CONTRACTED IN INSANITARY HOUSES

To the Editors of THE LANCET.

SIRS—In reply to Mr Smith's letter under this heading I beg to state that when a house is let furnished there is an implied warranty that it is fit for occupation (see *Wilson v. Finch Hatton Law Reports*, vol. ii. Exchequer Division 338, April, 1877), and if any injury or damage is suffered by the tenant, such injury or damage arising from any unfitness of the premises to be occupied (including illness caused by insanitary condition) then the tenant is entitled to compensation from the owner of the premises. I may add that, with certain exceptions no warranty is implied in the case of unfurnished houses.

I am, Sirs yours faithfully

HENRY A. JONES F.S.I. Special San. Sci. Cert.

Wellington street Strand, W.C. Feb. 8th 1893.

THE LOCUM TENENS AND INQUEST FEES

Enquirer—Such fees as all others, clearly belong to the principal and should be accounted for to him. It is perhaps charitable to suppose that the locum tenens regarded them as a perquisite, and there is something to be said for this view. But it is for the principal to take it and not the locum tenens, whose duty it is to report them and pay them to his principal on his return in the absence of any contract to the contrary.

Mr W. Sinclair Cameron.—Our correspondent has been treated inconsiderately. There is no virtue in acting so as to bring a good rule into disrepute. Our correspondent will be justified in claiming his usual fee. It will be time enough to strain a rule applying to medical men when the fee has been offered as it should have been offered in the first instance.

METEOROLOGICAL READINGS

(Taken daily at 8.30 a.m. by Steward's Instruments.)

5735

Medical Diary for the ensuing Week.

Monday, February 20.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M., Fridays and Saturdays, at the same hour
 ST BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Tuesday, Wednesday, Friday, and Saturday at the same hour
 ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, daily at 10 A.M.
 ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour
 CHELSEA HOSPITAL FOR WOMEN.—Operations 2 P.M., Thursday, 2 P.M.
 HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour
 METROPOLITAN FREE HOSPITAL.—Operations 2 P.M.
 ROYAL ORTHOPEDIC HOSPITAL.—Operations, 2 P.M.
 CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour
 UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M., Thursday, 9 A.M. Eye Department, 2 P.M.
 LONDON POST-GRADUATE COURSE.—Royal London Ophthalmic Hospital 1 P.M., Mr W Lang Diseases of Cornea.—101, Gt. Russell st. 8 P.M., Dr Galloway Lesions of the Genito-Urinary Tract.—Parkes Museum (Margaret-st. W.) 3.30 P.M. Dr Parkes Dwelling Houses
 CENTRAL LONDON THROAT AND EAR HOSPITAL.—5 P.M. Mr Lennox Browne Benign and Malignant Disease of the Faucial Tonsils (Post-graduate Lecture).
 THROAT HOSPITAL (Golden sq.).—5 P.M. Dr J W Bond External Operations on the Larynx.
 MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr Ralfe Some Clinical Features of Chronic Albuminuria.

Tuesday, February 21.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour
 Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
 ST THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M., Friday, 2 P.M.
 ST MARK'S HOSPITAL.—Operations 2 P.M.
 CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M., Saturday, 2 P.M.
 WESTMINSTER HOSPITAL.—Operations, 2 P.M.
 WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
 UNIVERSITY COLLEGE HOSPITAL.—Skin Department, 1.45 Saturday, 9.15.
 ST MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electrotherapeutics, same day, 2 P.M.
 ROYAL INSTITUTION.—3 P.M. Prof V Horsley The Brain.
 LONDON POST-GRADUATE COURSE.—Hospital for Skin Diseases, Blackfriars 4 P.M., Dr Payne Alopecia, its Varieties.—Bethlem Hospital 2 P.M., Dr T Hyslop General Paralysis of the Insane.—101, Great Russell st. 8 P.M., Dr Handfield Jones Polypl.
 PATHOLOGICAL SOCIETY OF LONDON.—Mr J Jackson Clarke A Critical Survey of Recent Work bearing on the Pathology of Cancer and Sarcoma. Observations on the same subject by Dr Ruffer, Dr Woodhead and Dr James Galloway
 ROYAL COLLEGE OF PHYSICIANS (Theatre of the Laboratories Examination Hall, Victoria Embankment).—5 P.M. Dr B A Whitelegge Changes of Type in Epidemic Disease (Murray Lecture)
 LONDON SKIN HOSPITAL (40, Fitzroy sq. W.).—8 P.M. Mr James Startin Ringworm and Alopecia.

Wednesday, February 22.

NATIONAL ORTHOPEDIC HOSPITAL.—Operations, 10 A.M.
 MIDDLESEX HOSPITAL.—Operations, 1.30 P.M., Saturdays, 2 P.M. Obstetrical Operations, Thursdays, 2 P.M.
 CHARING-CROSS HOSPITAL.—Operations, 3 P.M., and on Thursday and Friday at the same hour
 ST THOMAS'S HOSPITAL.—Operations, 1.30 P.M., Saturday same hour
 LONDON HOSPITAL.—Operations, 2 P.M., Thursday and Saturday, same hour
 ST PETER'S HOSPITAL, COVENT-GARDEN.—Operations 2 P.M.
 SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
 GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
 UNIVERSITY COLLEGE HOSPITAL.—Operations, 1.30 P.M. Dental Department, 9.30 A.M. Eye Department, 2 P.M.
 ROYAL FREE HOSPITAL.—Operations 2 P.M. and on Saturday
 CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M. Surgical Visits on Wednesday and Saturday at 9.15 A.M.
 LONDON POST-GRADUATE COURSE.—Hospital for Consumption, Brompton 4 P.M., Dr R. Maguire Sputum.—Royal London Ophthalmic Hospital 8 P.M. Mr A. S. Morton Ocular Paralysis.
 THROAT HOSPITAL (Golden sq.).—5 P.M. Mr T Mark Howell Affections of the External Meatus
 HUNTERIAN SOCIETY.—Mr Walter Rivington Certain Branches of Operative Surgery (Second Hunterian Society Lecture).

Thursday, February 23.

ST GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday 1.30 P.M. Ophthalmic Operations Friday 1.30 P.M.
 UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M. Ear and Throat Department, 9 A.M. Eye Department, 2 P.M.
 LONDON POST-GRADUATE COURSE.—Hospital for Sick Children Great Ormond st. 4 P.M., Mr W A Lane Acquired Deformities.—National Hospital for the Paralyzed and Epileptic 2 P.M., Dr Tooth Paraplegia.—London Throat Hospital (Gt. Portland-st.) 8 P.M. Dr Whistler Syphilis of the Throat and Nose.—Central London Sick Asylum 5.30 P.M. Dr Bristowe Cases in the Wards.
 CENTRAL LONDON THROAT AND EAR HOSPITAL.—5 P.M. Dr Dundas Grant Diseases of the Larynx.
 ROYAL COLLEGE OF PHYSICIANS (Theatre of the Laboratories, Examination Hall, Victoria Embankment).—5 P.M. Dr B A Whitelegge Changes of Type in Epidemic Disease (Murray Lecture)

Friday, February 24.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
 UNIVERSITY COLLEGE HOSPITAL.—Eye Department, 2 P.M.
 LONDON POST-GRADUATE COURSE.—Hospital for Consumption, Brompton 4 P.M., Dr R. Maguire Sputum.—Bacteriological Laboratory King's College 11 A.M. to 1 P.M., Prof Crookshank Leprosy and Glanders (Sections).
 CANCER HOSPITAL (Fulham road, S.W.).—4 P.M. Dr F A Purcell Cancer of the Rectum.
 UNIVERSITY COLLEGE CHEMICAL AND PHYSICAL SOCIETY.—3 P.M. Annual Public Meeting Prof Watson Smith Diseases Incident to Workpeople in Chemical and other Industries. Exhibition of Apparatus.
 CLINICAL SOCIETY OF LONDON.—8.30 P.M. Living Specimens at 8 P.M.—Dr Hector Mackenzie A case of Myxedema cured by Thyroid Gland Feeding.—Mr Betham Robinson Two cases of Congenital Luxation of the Head of the Humerus.—Dr Newton Pitt A case of Peripheral Asphyxia, Rheumatic Arthritis, and Extensive Deposit of Fibroid Nodules. And others Papers at 9 P.M.—Mr W Arbuthnot Lane Cases illustrating a New Operation or Dorsal Dislocation of the Head of the Femur, and some points in his Surgery of the Hip-joint.—Mr C. B. Lockwood Sequel to a case of Excision of the Head of the Femur and Erosion of the Hip-joint through the Anterior Incision, and with immediate and permanent Closure of the Wound.—Mr G H Makins A Note on the Prognosis of Sacro-Ilac Diseases, with three illustrative cases.—Mr Raymond Johnson A case of Lymphosarcoma of Tonsil Removed by External Incision with Preliminary Ligation of External Carotid Artery

Saturday, February 25.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and Skin Department 9.15 A.M.
 LONDON POST-GRADUATE COURSE.—Bethlem Hospital 11 A.M., Dr H. Corner Alcoholic Insanity

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office

Lectures, original articles, and reports should be written on one side only of the paper

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners. Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Publisher."

We cannot undertake to return MSS. not used

PUBLISHER'S NOTICE

IN order to facilitate the work of reference to the volumes of THE LANCET, we have arranged in the future to publish duplicate copies of the Index to each half yearly volume in a form in which they may be subsequently filed or bound together

We have had a large number of duplicate copies of the Index to the last half yearly volume printed, and those of our subscribers who may wish to be supplied with loose copies can obtain the same (without extra charge) on making application to the Publisher of THE LANCET

THE THYROID GLAND IN PHARMACY

IN connexion with the subject of the treatment of myxedema by means of preparations of the thyroid gland, Mr C B Allen of Kilburn writes—"It is quite an easy matter to prepare an ordinary mixture from the thyroid gland by selecting say twenty healthy lobes, carefully mincing and macerating them for twelve hours with two ounces and a half of a mixture of equal parts of glycerine and water, then adding ten ounces of chloroform water, frequently agitating for six hours longer filtering through paper, washing the mass with chloroform water till eighteen ounces have been obtained and adding to this ten drachms of tincture of orange and making up to one pint. Each ounce of this mixture contains the active principle of one lobe and the physician can

Communications, Letters &c have been received from—

ABSTRACT OF

The Goulstonian Lectures

ON THE

CHEMICAL PHYSIOLOGY OF THE ANIMAL CELL

Delivered at the Royal College of Physicians on Tuesday March 7th,

By W D HALLIBURTON, M.D.,
FRCP LOND, FRS,

PROFESSOR OF PHYSIOLOGY KING'S COLLEGE, LONDON

LECTURE I.

THE MICRO-CHEMISTRY OF THE CELL.

[In his preliminary remarks Dr Halliburton thanked the College for the honour conferred on him, spoke of the important influence of the cell theory in all branches of science and alluded to the difficulties attending chemical investigations on living things. He further announced that the three lectures he had to give would deal with (1) the micro-chemistry of the cell, (2) the proteid constituents of the nucleus and cell protoplasm, and (3) the coagulation of the blood. He then proceeded as follows.]

The earlier observers on the animal cell, following the lead of the botanists described a cell wall as one of its necessary constituents. We now know that a cell wall is an exception rather than the rule, and our definition of the animal cell is that of a mass of living substance or protoplasm containing a nucleus in its interior. To this we must now add at least for some cells that another body called the "attraction sphere" by van Beneden is also present. This attraction sphere becomes intermingled with the nucleus during the progress of cell division, and no doubt it is this body rather than the nucleus that takes the lead in the division of a cell into two. The nucleoli are believed to be collections of reserve material which enter into solution when cell division commences and perhaps contribute to the formation of the thread like structures into which the substance of the nucleus is resolved. There can also be little doubt that the nucleus exercises a controlling influence on the nutrition of the cell. By certain fluids a vegetable cell can be broken up or plasmolysed into separate little masses of protoplasm. Those fragments which are without a nucleus are no longer able to form starch.

Passing now to the functions of the cell as a whole, we find a great contrast between those exercised by the single cell of the unicellular organism and the many cells of the multicellular animal. To the anatomist the single egg cell or the amoeba is an extremely simple object. To the physiologist, on the other hand, simplicity of structure means an increased difficulty in understanding function. In the higher animals certain cells are set apart specially to perform one function, certain other cells to perform another, some, for instance, are concerned in muscular contraction, others in elaborating secretions, others in reproduction and so forth. But in such an animal as the amoeba all these functions—movement, secretion, digestion, excretion and multiplication—are performed by one cell. In the higher animals the various functions are unravelled from each other, but in the amoeba, looking at its apparently simple structure, it is difficult to realise the potentialities of and the variety of functions inextricably blended in, the little mass of living jelly. Whilst a cell is alive it is always undergoing certain chemical changes. It is in a state of unstable chemical equilibrium. The series of changes beginning with assimilation and ending with excretion is what is known as metabolism, and adopting Gaskell's nomenclature, constructive metabolism may be termed 'anabolism,' and destructive metabolism 'katabolism.' Microscopic investigation has shown us that protoplasm itself is not homogeneous it is not even merely loaded with granules but pervading it is a network of irregular arrangement in such an undifferentiated cell as the white blood-corpuscle, and regular arrangement in such cells as muscular fibres where the movement is limited to one direction. Different histologists have given different names to these two portions of protoplasm. The most convenient names are those introduced by

Schäfer he calls the spongework of fibrils "spongioplasm," and the more fluid homogeneous part which flows in or out of the spongioplasm 'hyaloplasm.' Carnoy believes that the reticulum itself consists of a material called "plastin," a substance the nature of which we shall have to inquire into later on. In addition to this there are the granules embedded in the protoplasm which stain differently with different reagents, and in some cells there are vacuoles or spaces filled with a watery albuminous fluid, sometimes acid and sometimes alkaline. The contents of granules and vacuoles are termed "paraplasm." It will be convenient to take the contents of the vacuoles first. In unicellular organisms, like the amoeba, solid particles when ingested are surrounded with fluid, this fluid appears to play the role of a digestant poured out by the animal in its attempts to dissolve the solid particles. Other vacuoles, such as the contractile vacuole of the amoeba, are excretory. We next ask, What is the composition of the granules that pervade the protoplasm? These are sometimes of a fatty nature and are well seen in the leucocytes after a diet containing fat, they stain black with osmic acid. Sometimes, especially after a carbohydrate diet, and particularly in liver cells they are composed of glycogen and stain brown with iodine in some unicellular animals they appear to be of an inorganic nature, but by far the most constant granules are those which, like the rest of the protoplasm, are albuminous or proteid in character. The behaviour of these to stains shows that these again may be subdivided into various classes. Proteid, in fact, constitutes the main bulk of the solid matter in all living parts of organisms, animal and vegetable. The proteids obtainable fall into two chief groups the globulins and the nucleo-albumins. The characters of the individual members of these groups I shall take up in my next lecture. But other substances besides proteid are obtainable from cells. Of these the most constant are *lecithin* a phosphorised fat, *cholererin*, a monatomic alcohol, and a small percentage of inorganic matter in which calcium, magnesium and the alkaline metals are combined with phosphoric acid and chlorine to form phosphates and chlorides respectively.

Our next consideration is a more profound one, and that is In what condition are these substances present in the cell? Are they separate, merely in a state of chemical admixture, or are they combined one with another? Here we enter the realm of uncertainty. We can only say that the almost constant association of proteid with lecithin suggests something more than mere admixture and that the difficulty of separating proteid from inorganic salts, especially from calcium, indicates very forcibly that they are combined together. In addition to this, however there are very strong indications that the proteid of a living cell is in a different condition from the proteid of a dead cell. The distinction between living and non living proteid was first suggested by Rudolphi in 1821 and emphasised by John Fletcher in 1837, but it was not until 1875 that an intelligible theory to explain such difference was advanced by Pflüger. The non-living proteids, such as are contained in white of egg are stable and indifferent to neutral oxygen but when these proteids are assimilated—that is become part of a living cell—the molecules of proteid live by breathing oxygen—not necessarily oxygen from without, as frogs kept in chambers free from oxygen will continue to live for many hours and give off carbonic acid formed from the oxygen stored in the tissues. The assimilation of a proteid is probably due to the formation of ether like combinations between the molecules of living proteid and the isomeric molecules of the food proteid, water being eliminated, this process of polymerism producing large and heavy but still simple, molecules. In this process the nitrogen of the non living proteid leaves the hydrogen with which it is combined in the form of amidogen (NH_2) and enters into combination with carbon to form the more unstable substance cyanogen (CN). We thus find ureic acid, creatin, guanin &c. as products of proteid metabolism, whilst none of such cyanogen-containing bodies are obtainable from non living proteids.

Leaving this question for a time and passing to other methods of research, the inquirer should next ask the chemical meaning of the staining produced by the pigments used in histological investigation. Staining reagents are primarily employed to bring out structure, the cells as they occur in nature are too transparent to allow of a thorough investigation of their contents. They must be fixed by such reagents as osmic acid, that produce as little change as possible in their appearance and their structure can be

revealed by the subsequent use of pigments, because certain of their parts are more deeply stained than others, the nucleus, as a rule, standing out conspicuously. It cannot be doubted that this is due to differences in their chemical composition.

The histologist's staining reagents fall into two main groups—1. *Metallic compounds*, such as silver nitrate, gold chloride and osmic acid. In this case the staining is produced by the reduction by the tissue of the compound and the deposition of the metal in the situation where the reduction has occurred. 2. *Dyes*, such as logwood, carmine &c. Our chemical knowledge of many of these stains is not very great, but there is a considerable amount of chemical knowledge concerning one important class of dyes—namely, those known as the aniline dyes. The methods of using these reagents are two in number—some are applied directly to the preserved tissue, or, it may be, to the fresh tissue just removed from the body, whilst in other cases the pigment is injected into the circulation and its effects observed when the animal is subsequently killed. Both methods have yielded valuable results.

[The lecturer then gave several instances in illustration.] Ehrlich's experiments with methylene blue and similar pigments have greatly assisted our understanding of oxidation processes in different tissues. If a saturated solution of methylene blue is injected into the circulation of a living animal, and the animal killed a few minutes later, it is found on opening the body that most of the organs present their natural colour, although the blood is dark blue. On exposure to the oxygen of the air all the organs in time become blue. The avidity of the tissues for oxygen has been so great that they have been able to decompose the methylene blue molecule, forming a colourless reduction product which on exposure to the air takes up oxygen and becomes blue again. From such an experiment one can understand the power of the tissues in the reduction of oxyhæmoglobin, and moreover the fact that the different tissues vary in tint in the methylene blue experiments enables us to localise those situations where reduction is most actively carried on. There appears to be a great future in the place that aniline dyes will occupy in elucidating physiological and pathological problems. Dr. Sheridan Delépine divided aniline dyes into two classes, acid fuchsin may be taken as a type of the first, basic fuchsin of the second. The first class stains deeply the most differentiated, the second the least differentiated portions of cells. In a drop of blood the red corpuscles are most deeply stained by acid fuchsin, the leucocytes being but faintly stained, whilst the nuclei are not stained at all. If basic fuchsin is used the nuclei are stained most deeply, the protoplasm of the leucocytes to a less extent, and the red corpuscles least of all.

[The lecturer then proceeded to give a more detailed summary of Ehrlich's discoveries, and continued.]

But my chief object in dwelling on these so long is to clear the way for the subject I propose to treat in the third lecture, the coagulation of the blood, as the behaviour of the white corpuscles in that process lies at the very root of the matter. I next propose to sketch two other lines of research with their results, in which micro chemistry has played a conspicuous part. I refer to the detection of iron and phosphorus in the cells. Hæmoglobin has long been known as a proteid like substance which differs from other proteids in containing iron. It is undoubtedly the principal iron containing constituent of the body. In recent years other iron holding compounds have been found in cells, and these appear to be either forerunners of hæmoglobin or the result of its disintegration. This subject has been taken up by Quincke, Zaleski and Bunge on the continent, by Drs. Mott and Hunter in this country, and by Macallum in Canada. Without treating the subject in the chronological order of discovery we may take Bunge's work as a very convenient starting point. He found in the yolk of the hen's egg a proteid like substance which, like the chief chemical constituent of cell nuclei, contains a high percentage of phosphorus. It is, in fact, a nuclein, but more than that, for its molecule contains iron in addition. From the very reasonable supposition that this material is the mother substance of the blood pigment Bunge named it "hæmatogen." Hæmatogen is also found in milk in small quantities and can be further separated from many vegetable tissues which are used as food. The resemblance to the nuclein of cell nuclei suggested that perchance the nuclei also contain iron, and this question was taken up by Macallum. Although probabilities pointed to the nuclei as the situation where the iron occurs, the chain of evidence was not complete until the micro chemical methods next to be mentioned actually demonstrated its presence there, and it is to

Quincke, Zaleski and Macallum that we owe these methods. Zaleski recommends the blue or green colour produced with potassium ferro or ferri cyanide and hydrochloric acid. Macallum, using alcohol hardened tissues, soaked them for varying periods in ammonium sulphide solution, and found that the nuclei were coloured greenish, this after some weeks became a rusty brown, owing to the formation of ferric oxide. This was true for all cells examined, including those in situations like epithelium and cartilage, where there could have been no possible contamination with hæmoglobin. The fact that the chromatin masses in the cells during their transference to the fœtus from the placenta also give similar reactions is another proof that this is the method by which the fœtus receives its supply of iron, and, further, the nuclei of vegetable cells do not differ from animal cells in the presence of iron within them.

Passing now to the other side of the problem, from the forerunners of hæmoglobin to the products of its disintegration, we find that the liver has been the chief field where investigators have by similar methods advanced our knowledge. There are certain conditions in which the destruction of portal blood can be experimentally increased, as by the administration of the drug toluyldiamine (Engel, Kiener, Hunter), the importance of this experiment arises from the similarity between the effects observed and those found in nature's experiment, the disease of pernicious anemia. In these conditions of excessive blood destruction chemical analysis reveals increased accumulation of the iron in the liver and in some cases in the spleen, also chemico histological research shows the portal zones of the liver lobules to be crowded with albumino ferruginous granules, and clinical observation harmonises with the foregoing in the increased colouration noted in the urine produced by urobilin, an iron free constituent of the blood pigment (Mott). The liver, however, is not merely the seat of blood destruction, but it is also the seat of, at any rate, the beginning of hæmoglobin formation. Bunge has demonstrated most conclusively that iron is present in greater proportions in the livers of new born animals than in older ones, it thus acts as a storehouse of iron subsequently used in the formation of red corpuscles, and Delépine believes that this function persists throughout life. Iron, so far as our bodies are concerned, is a very precious metal, the intake is usually small, as also is the output. There are other practical aspects of this iron question which, when speaking to physicians, I feel bound to notice in passing. First, in relation to diet, especially of young children, it is important that these should have, after a certain time, food which contains a proper proportion of the hæmatogenous constituent. The formation of blood, as of the other tissues, is at this time much more active than at later periods in life. Experiments on animals show that they rapidly become anæmic and waste when deprived of hæmatogen, even though inorganic compounds of iron are given instead. They enter the world with a store of iron in their livers—an extra supply derived from the maternal tissues—to set them up for the first few weeks or months. They can therefore, live for this time and thrive perfectly well on milk, poor though it is in hæmatogen, but after this time—a time which varies in different animals—it is a necessity that further hæmatogen should be administered. It may be given in various forms for there appear to be many varieties of hæmatogen, and in animals this is usually obtained from vegetable food. There is no doubt that the anemia which is seen in children who are weaned late is in part the result of this poorness of milk in hæmatogen. This leads me to speak in the next place of the administration of iron medicinally. The quantity of iron in the whole body is only three grammes, and this amount is taken many times over during treatment. Bunge explains the usefulness of iron in chlorosis by its forming iron sulphide in the intestines, removing in this way excess of sulphur from the body, in chlorosis there are excessive fermentation processes in the alimentary canal and large quantities of sulphuretted hydrogen are formed, which destroy the organic compounds of iron that form hæmoglobin, the administration of iron thus prevents this destruction of hæmatogen. I cannot but think that this explanation, though accounting for the facts in part, does not contain the whole truth. As Landwehr points out, it hardly explains the limitation of the disease to the females and the period of early adolescence. Landwehr's own explanation, in which the substance he discovered and named "animal gum" plays a conspicuous part (and according to him does so in most physiological processes), is certainly not so feasible as Bunge's and thus it becomes of great scientific importance that the truth of the hypothesis

should be put to the test of experiment. This has already been done in a few cases by Dr Hale White. He has treated cases of chlorosis with hydrochloric acid, a substance which undoubtedly lessens putrefactive processes, but although the patients improved somewhat they did not mend any more rapidly than others who were simply treated with rest in bed and wholesome food. Dr Mott suggested to me that attempts should be made with bismuth, this, like iron, forms an insoluble sulphide and, if Bunge's theory is true, ought to be as beneficial in anæmia as iron itself. I am not aware that this has yet been done.

But I must now leave the question of iron and pass on to the other element with the micro chemical detection of which we have to deal—namely, phosphorus. As has been already mentioned, it is in the nucleus that the most important of these phosphorised proteid like substances chiefly occur.

[The lecturer then gave details of the histology of the nucleus, and continued.]

Histology teaches us the complicated nature of the nuclear structures, the various names of the materials found were originally given from their microscopic appearances rather than from their chemical properties. The method of gastric digestion enables us to obtain nuclein in large quantities because the rest of the cell is dissolved. Nuclein is, in fact, a substance of which there is a considerable amount of accurate chemical knowledge. But there is another micro chemical method which promises to be of as great value as that of gastric digestion, and it is to this that I have been leading up. It has only been quite recently introduced, and its object is the microscopic localisation of phosphorus. Lillenfeld and Monti¹ are the workers to whom we owe the method, and it consists in taking sections or teased portions of fresh tissues and organs and soaking them in a solution of ammonium molybdate. If phosphorus is abundant and present in the form of simple compounds like phosphates, the yellow colour of the preparations is visible to the naked eye within a few minutes, whereas, if the phosphorus is present in a more complex union the time required is longer and the microscope may be necessary to detect the yellow colouration. After this the sections are transferred to a 20 per cent. solution of pyrogallol dissolved either in water, or, which is better, in ether. The sections are dehydrated, clarified, and mounted in Canada balsam. The action of the pyrogallol is to reduce the phospho-molybdate, and the resulting colouration is brown or black according to its intensity.

[Lillenfeld and Monti's chief results were then summarised. Amongst other instances, the lecturer remarked.]

In nervous tissues, as one would expect from the nobly phosphorised nature of their constituents the staining was very intense, and in nerve cells the cell protoplasm was stained even more deeply than their nuclei. In conclusion, let me, in a few general terms, sum up what I have been saying. We have followed a number of divergent lines, all, however, starting with the cell, and all further connected by the link of micro-chemical investigation, but they have led us here and there into digressions in which the cell as such, has been left far behind. Let me now proceed to gather up these scattered strands. We have seen that, in order to obtain a chemical knowledge of the cell, it is necessary to have, in the first place, an accurate knowledge of its anatomy, but that the histological methods of staining and so forth depend on a chemical basis. The main substance of the cell is proteid, and this proteid when in the living cell is intramolecularly different from that in non living protoplasm. In addition, there are smaller quantities of lecithin, cholesterol, and inorganic salts. As the result of their vital activity cells form various products, some of these, like carbonic acid and urea, are the result of oxidation, and these products of destructive metabolism leave the cell and are ultimately got rid of by the excretory organs. Others like glycogen and fat, may be for a time stored up in the protoplasm, and it has long been known that these can be detected by the use of iodine and osmic acid respectively. More recent micro chemical methods have taught us that the important elements iron and phosphorus can be also localised in the cell or in its nucleus and on account of the newness of these investigations I have dealt with them at considerable length, pointing out on the way, what I conceive to be some of the practical bearings of the results of such inquiries. But in addition to such facts there are others concerning which the present state of our knowledge does

not allow us to pronounce positive chemical opinions, and here I would again allude to the important work of Ehrlich on the behaviour of protoplasmic granules to the aniline dyes. The fact that these dyes are, some acid, some alkaline, and some neutral, would seem to indicate corresponding differences in the reaction of the granules themselves. The reaction of living protoplasm as a whole is alkaline, but there are various acid products formed as the result of protoplasmic activity, such as carbonic acid, lactic acid, uric acid, and in one well-marked case that of the gastric cell, hydrochloric acid. It appears to me more than probable that during life the reaction of the protoplasm or of parts of the protoplasm is a changing one, the reaction may be in an unstable condition of equilibrium as the other factors of cell life are. We know that when the circulation ceases and the cells can no longer build themselves up from new material, but are still sufficiently living to continue their retrogressive or katabolic changes, they become acid from the accumulation of such substances as lactic acid or from the formation of acid phosphates. This tendency to become acid is being constantly corrected by anabolic or assimilative changes during healthy cell life, and it seems quite possible that in Ehrlich's staining processes we have an actual proof of this condition of unstable chemical reaction, this appears to be very strikingly confirmed by a recent experiment of Hardy and Kanthack,² who found that eosinophile cells after feeding on bacteria become amphophile. But, leaving such speculative propositions and coming to our positive knowledge, none can deny the enormous impetus that has been given to chemical physiology by the combination of the use of the microscope with that of chemical reactions. Valuable as micro-chemistry is, however, as a means of research it cannot go very deeply into the matter, and happily we can supplement the knowledge so obtained by the methods of macro-chemistry. We have already made the acquaintance of nuclein, the chief material in the nucleus, and of the various proteids contained in the cell protoplasm, and it will be my duty in my next lecture to develop this aspect of the subject more fully.

The Milroy Lectures

ON

CHANGES OF TYPE IN EPIDEMIC DISEASES.

LECTURE III

Delivered at the Examination Hall, Victoria Embankment on Feb 28th, 1893

By B A WHITELEGGE, M D, B Sc LOND

Prevalence determined by External Conditions — Not accompanied by Change of Type — All Epidemics — Water Epidemics — Seasonal Prevalence — Accumulation of Susceptible Persons

MR PRESIDENT AND GENTLEMEN,—Although change of type is an important factor in determining the fluctuations in prevalence of epidemic diseases, it is not the only factor. Wide diffusion may take place without increased severity and, indeed, it is not an uncommon experience to find that sudden epidemic extension is accompanied by apparent lessening of average severity and lowering of the case mortality. This involves no real exception to the general rule that the tendency to epidemic diffusion is greatest when the intensity is at its maximum. There are obviously three principal classes of conditions upon which epidemic prevalence depends. (1) The energy of the contagium itself, its power of withstanding hostile influences and of overcoming resistance, (2) the facilities for transmission of infection to susceptible persons, (3) the susceptibility of the individuals upon whom the contagium is to be grafted. The conditions which come under the second head include the varying degrees of proximity, from the closest contact to complete isolation, atmospheric states favourable or unfavourable to diffusion, and transmission by other media, such as water or milk. These are constantly changing, and, however orderly the rise and fall of intensity may be, the prevalence will be modified

2 In the Annual Summary for 1890 the Registrar General states "It appears from the records of the London Fever Hospital 57 that out of an equal number of cases of enteric fever about many die in a quarter of the year as another the spring quarter however showing a slightly greater fatality amongst its cases than one of the other three." It is not to be anticipated that hospital would include a full proportion of the slighter attacks, but it from the above observation that even amongst those of sufficient to bring them into hospital there is some indication of higher mortality at the period of spring minimum.

the periods of record being different the two curves are not together parallel, the winter maximum being far more marked in the death curve, based upon fifty years' statistics, than in the hospital curve, which relates only to the fifteen years 1876-90. But in an earlier chart of similar character³ the concurrence is closer, and in both instances the contrast in range is very striking and confirms the relation between maximum seasonal prevalence and lessened average fatality of attack. We may conclude, from the difference between the two admission curves referred to that small pox since 1830 has somewhat altered its seasonal curve, the spring maximum having become much more prominent and the winter maximum less so. The differences between the death curve and admission curve for scarlet fever are slight, and notification statistics⁴ afford a clearer contrast. Still the attacks, measured in either way, rise higher above their mean in autumn, and fall further below it in spring, than do the deaths, and the same inference of lessened case mortality in time of seasonal prevalence may be drawn. As regards measles there are few data for comparison, but Dr. Harvey Littlejohn⁵ has given us the seasonal curves of deaths and notified attacks for the ten years 1880-89 in Edinburgh. They are closely parallel, and, so far as the principal maximum in spring is concerned, there is no indication of altered case mortality, the crests being of equal height, but the attack curve falls rather lower than the other at the minimum, and the smaller maximum in December is more marked in the attack curve than in the other. At all events there is no evidence of increased case mortality accompanying the seasonal prevalence. The epidemiological character of measles is such as to render it unlikely that any strong contrast would appear. The epidemics are brief and widespread and the attacks which bridge over the intervals are few. Hence the data, including the monthly means of attacks and deaths, are made up almost exclusively of the records of epidemics, the attacks and deaths during the intervals being too few to materially affect the averages or to afford a basis for comparison.

Amongst certain diseases of mobile type, and particularly those which are dependent upon changes in the soil, the seasonal curve has a different meaning. The seasonal maximum of prevalence is dependent upon increased virulence, and the severity of attack is greatest at that time. The lowered case mortality of enteric fever during the autumnal prevalence divides it sharply from the purely telluric group in this respect. Diphtheria again, is liable to rapid change of type, and it may be that seasonal conditions bring about intensification as well as wider diffusion of the contagium. The notification figures quoted by Dr. Thorne Thorne⁶ lend some support to the idea that the case mortality in diphtheria is, on the whole, increased during the autumn maximum, but further evidence is wanted. It would seem that, in small pox at all events, the seasonal curve is of wider range during periods of greater epidemic intensity than at other times. Buchan and Mitchell⁷ found that this was the case in 1870-71-72 to a very marked degree as compared with the other years for which records were available. Indeed, the figures given by them show a gradation in this respect in successive quinquennia, from the point of minimum mortality in the fifties to the great epidemic of the early seventies, a gradation which is in keeping with other indications of progressive change in the character of small pox during that period. In the following table the range of the mean seasonal curve for each group of years is measured roughly by the percentage excess of the January maximum over the September minimum—

Table of Small pox Deaths in London

During	Deaths in first four weeks of January	Deaths in last four weeks of September	Percentage excess of maximum over minimum.
1840-44	485	345	41
1845-49	462	288	60
1850-54	317	207	53
1855-59	263	217	21
1860-64	324	233	39
1865-69	406	228	78
1870-74	934	372	165

⁵ Ten Years' Compulsory Notification of Infectious Diseases in Edinburgh.

⁶ Diphtheria, its Natural History &c. p. 32.

Journal of the Scottish Meteorological Society 1876.

From this it appears that, as the destructiveness of small-pox increased in the sixties, so did the range of its average seasonal curve. If, however, the quinquennia are traced backwards from the time of least mortality in the direction of the previous great epidemic of 1838, the otherwise accordant indications are interrupted by a conspicuous lessening in intensity of the seasonal curve in the years 1840-44. Another point of some interest in connexion with the seasonal curves of infectious diseases is that they are often bolder where climatic changes are more intense and more orderly. This is seen, for example, upon comparing the curves of small pox, measles, diphtheria, or enteric fever (not, however, of scarlet fever or whooping cough) for London and New York respectively.⁸

The varying incidence of infectious diseases at different seasons is no doubt dependent directly or indirectly, upon climatic conditions. It has been suggested that social relations have much to do with it there being closer aggregation in doors in the colder months, but this explanation is negatived by the want of uniformity amongst the diseases in question. Some infectious diseases are most prevalent at the beginning of the winter, others at the end. Scarlet fever reaches its maximum in England in October in Germany and Scandinavia in January, in New York in May. Further than this the rise begins long before the maximum is reached, so that if it be alleged that the commencement of winter-conditions causes the maximum of scarlet fever prevalence to be reached in October it would still be necessary to explain why the rise begins as far back as May. Perhaps the most unequivocal instances of a seasonal prevalence of disease dependent upon social conditions are those which arise from the difference in risk of exposure to infection on Sundays as compared with other days of the week. Thus the rash of small pox has been stated to appear more often on Sunday than on any other day of the week amongst domestic servants, the usual interval between infection and rash being fourteen days and the chance of out-door infection being often limited to Sunday. The notification records at Nottingham show a very decided minimum in the number of onsets of scarlet fever on Wednesdays corresponding, as it would seem, to a maximum risk of infection on Sundays.

THE CHOLERA EPIDEMIC IN RUSSIA

By FRANK CLEMON, M.D. EDIN. &c.

No I

IN CENTRAL ASIA AND SIBERIA.

SINCE 1872-73 no epidemic of cholera has occurred in Russia that can compare in violence and extent with the recent outbreak. The disease still lingers in some parts of that empire, but these bear but a small proportion to those in which it is extinct, and it is now possible to gather from the completed returns some impression as to the severity of the epidemic of 1892. Daily reports have been received from every part of the country by the authorities at the Medical Department of the Ministry of the Interior in St. Petersburg but these have in many instances been supplemented by later and fuller reports so that the final totals are considerably greater than the sum of the daily ones would be. With regard to the authenticity of the figures given in this and the following articles it should be stated that they have been in every case obtained directly from the authorities just named. The liability to error particularly where the figures are derived from such distant and sparsely inhabited regions as those which form the subject of the present article, is obvious, but the Russian Government has spared no effort to obtain as complete returns as possible and I am assured by the Director of the Medical Department that in no case does the error exceed 10 per cent. It is proposed here to trace briefly the course of the epidemic throughout the Russian empire.

The cholera reached Russia direct from Persia. It threatened her frontiers as soon as it appeared in Meshed, which is little more than 100 versts from the line which separates the two countries. As Meshed may be looked upon as the nidus from which the disease spread to Russia, it may be worth while to look a little closer at the nature of this town. Meshed

⁸ Buchan and Mitchell, Journal of the Scottish Meteorological Society, 1878.

is a place of considerable importance, it is the capital of Khorassan and is one of the most densely populated cities of Persia. It is joined by a good road with Ashkhabad, the chief town of the Russian province of Transcaspia. In Meshed are found the mosque and tomb of the holy Imam Riza, a highly venerated saint amongst the Shute Mohammedans, and consequently there is an almost constant flow of Mussulman pilgrims visiting the shrine from various parts of the country. That they come from both sides of the frontier is proved by the fact that on the Transcaspian Railway a time table has been published in the Persian language and bears a portrait of the Shah to induce the faithful to avail themselves of the railway in their pilgrimages. Cholera appeared in Meshed in May, 1892. A telegram in *The Times*, dated May 26th, stated that up to that date thirteen cases had been reported.¹ It may have existed there for some time before this date, as on the 31st (19th, Old Style) it had passed the frontier and appeared in Kachka, 130 versts (eighty seven miles) from Meshed. Kachka was the starting point of the epidemic in Russia, the point of inoculation whence the disease spread throughout the country. The local manifestations were not, however, very severe. From May 19th² to June 10th there were, in all, forty five cases with forty one deaths. It is not unlikely that there were more cases, but unreported, which would reduce this appalling death rate. Kachka is a town lying in the midst of a more or less barren steppe north of the Persian frontier. It consists of an *aul*, or Turcoman settlement, a Russian town, and a station on the Transcaspian Railway, about 120 versts from Ashkhabad on the west and 200 versts from Merv on the east.

The effect which the opening of new railways or other means of communication has on the course of epidemics is an interesting problem. The present epidemic of cholera has spread through Russia with unprecedented rapidity, which may be most plausibly explained as the result of the laying down of many new railways and of the increase in the number of people who travel by rail. By far the most important of the new lines which have been opened since the epidemic of 1872-73 is the Transcaspian Railway. This line, it will be remembered, was projected in 1880 and carried out by General Annonkoff, through whose energy the last part of the line was finished in an incredibly short space of time, and the completed railway to Samarcand was triumphantly opened on the anniversary of the Czar's coronation in the spring of 1888. Originally intended as a purely military railway, and still under the control of the Ministry of War, it has proved, nevertheless, of great commercial importance, and carries large quantities of goods and passengers. It has shortened the journey between Samarcand and the Caspian Sea from the many days which were formerly needed, when camels formed the sole carrying power, to the comparatively short period of sixty hours. Beginning at Oozoon Ada on the Caspian Sea, the line runs through Ashkhabad, Merv and Bokhara to Samarcand, where, for the present, it ends. For the greater part of its course it runs over almost barren steppes, bordering the desert of Kara Kum, until it crosses the great Amu Daria river (the ancient Oxus) and enters the rich and fertile valley of the River Zerni shan, along which it runs to Samarcand. Kachka is a station about 370 miles from the Caspian terminus of the railway, and for this distance the line runs to the north of, and parallel with, the Kopet Dag mountains, which here form the natural frontier of Persia.

As the soil (or, rather, variation in the moisture of the soil) has been thought to play an important part in the spread of cholera, it may be interesting to note its nature in this district. The correspondent of *The Times*, who travelled over the line immediately after its opening, writes³ "The best characterisation of the whole surface of the country is to divide it into sand steppes, salt steppes and grass steppes, the last-named being the so-called oases interspersed between the other two. With few exceptions all the sand steppes manage to nourish the short and knotty shrub called the 'saxaul,' which strikes its hardy roots down to a wonderful depth, sometimes ten or twelve feet, into such soil as it can find, and appears on the surface like a thin and scanty gooseberry bush, varying from a foot to five feet in height, at inter-

vals of five, ten, twenty, or perhaps forty feet, all over the plains as far as the eye can see. As soon as the great heats come on, the saxaul gets scorched up and assumes a similar colour to that of the dusty drab steppes." Where there is none of this plant the sand steppes "present nothing but shifting sand, driven up by the winds into hills of all shapes and sizes, destitute of vegetation and interspersed with salt lakes and pools." The salt steppe is even flatter than the sand steppe, as it is unaffected by the wind. It is "aked over with a thick crust of whitish clay or marl, impregnated and faced with salt, which crystallises perfectly white on the surface, like snow, especially in the sunken spots or salt pans left by the rainpools. Salt here for the most part takes the place of sand and glitters brightly in the glare of the sun." In the oases, on the other hand, which form about 10 per cent of the whole of the country of Transcaspia, the soil is very rich and fertile. It has received in Russian the special name of "loess," or white earth, in contradistinction to the "tchernozem," or black earth, which gives the southern provinces of Russia their fertility. It is found only near the streams which water this sandy plain. In the stretch of country between Kachka and the Caspian Sea (the highway by which cholera entered Europe this year) the watercourses are very small and few in number, thus differing from the eastern section of the railway, where the large streams of the Tedjent, the Murghab, the Amu Daria and the Zerni shan produce a fertile soil and allow of a growth of luxuriant vegetation. The small streams of the western half of the line come from underground sources at the foot of the northern slopes of the Kopet Dag mountains, where the rainfall is only about half of what it is on the southern, or Persian, slopes.

Another important feature of this district is the occurrence at times of inundations from the overflow of these usually small and insignificant streams. After severe storms they become rushing torrents and overflow the country in an extraordinarily brief space of time. In the early days of the railway these inundations were almost as great a difficulty to contend with as the shifting sands, and it not unfrequently happened that considerable stretches of the line were torn up by the violence of the floods, but the water subsides as quickly as it rises, either absorbed by the sands or evaporated by the great heat, and in a few days land that was completely under water may be seen beginning to split into cracks and fissures from the heat of the sun.

It is interesting to note the behaviour of the cholera epidemic in this salt and sandy desert. Mr Macnamara in his "History of Asiatic Cholera," writes "After a careful study of the history of the disease a desert appears to me to be the only country in which cholera is unable to establish itself, the disease speedily dies away in an arid waste of this description." The epidemic of last summer lingered for some three months in the province of Transcaspia, but, with the exception of the town of Ashkhabad, no part of the province suffered severely from the disease. The total number of cases reported was 2800 and of deaths 1517, the ratios per 100 000 inhabitants being 400 and 217 respectively, figures in marked contrast with those furnished by the neighbouring fertile provinces of Turkestan. I proceed to trace in more detail the course of the epidemic.

As stated before, there were in Kachka between May 19th and June 10th forty five cases with forty one deaths. Between June 10th and 30th there were, in addition, thirty one cases with thirteen deaths. After the 30th Kachka ceased to appear in the official lists, so that presumably the epidemic had ceased there. On May 25th cases occurred in Oozoon Ada, the sandy terminus of the Transcaspian Railway on the shores of the Caspian Sea, and in the next three days three Persians died of cholera. Apparently the intervening stations were not affected so early as the terminus. Whether this was the fact, or whether cases occurred which have not been officially reported, it is impossible to say. It is conceivable that the Persians contracted the disease in Kachka and did not sicken till after their arrival in Oozoon Ada, the journey taking twenty two hours and a half by fast train and less than thirty six hours by slow train. The next reported cases occurred amongst a detachment of troops coming from Merv and going into camp near Ashkhabad. Between June 4th and 10th four men died, and on the last date there remained nine severe cases and twenty three suffering from diarrhoea. During that time two children died from cholera in Ashkhabad. This town is the capital of Transcaspia, it contains a population of 10 000 and is the most important station on this section of the line. It was destined later to be the scene of a most violent outbreak of the disease, but at the beginning

¹ It is stated (*Brit. Med. Jour.*, vol. I. 1892, p. 1153) that thirteen cases occurred in Meshed between May 10th and 14th. These dates were probably Old Style dates. The 14th Old Style is the 20th, New Style.

² Henceforth all dates mentioned are Old Style dates.

³ *Russia's Railway Advance into Central Asia* by George Dobson p. 147. London, 1890.

the numbers were small. On June 14th and 15th there were seven cases but only one death, whilst in the neighbourhood (presumably in the camp before mentioned) there were thirteen cases with five deaths. On the 18th, cases first appeared amongst the Turkomans in the *cosl* of Ashkhabad and in four days there were twenty-four cases with eleven deaths. Onwards to the end of June there were, in all, fifty cases, but the number of deaths is not stated. During the first half of July the numbers remained comparatively light, but on the 23rd there was a sudden and extreme rise in the numbers of cases and deaths. At that period there was intense heat and a close and sultry atmosphere throughout the day and night, and it is not unimportant to note that there was also an unusual abundance of ripe melons, of which the Russians are at all times extremely

In the accompanying chart the relation of the rise in the intensity of the cholera epidemic in Ashkhabad to the rise in temperature is shown diagrammatically. For the daily temperatures I am indebted to the secretary of the Central Physical Observatory in St. Petersburg.

Between Ashkhabad and Oozoon Ada there is no town of any size save Kizil Arvat, which has never appeared separately in the lists, any cases which occurred there being included under the general heading of Transcasian province. Oozoon Ada, important only as being the terminus on the Caspian Sea of the Central Asian Railway, was at no time severely affected, the total number of cases between May 25th and July 9th being seventy, and of deaths twenty-five. It may be mentioned in passing that the chief water supply of this town, as also of Krasnovodsk, which lies a short distance to the

Diagram to illustrate the course of the cholera epidemic in Ashkhabad during the last half of July 1892 and the temperature of the place for the same period. The average daily returns for the first half of July were six cases and three deaths. From the 14th to the 21st no returns had been received. The temperature curve has been obtained by taking the average of three daily observations.

food. On July 23rd there were no less than 372 cases with 110 deaths, on the 24th there were 172 cases with 163 deaths, and on the 25th 117 cases with 63 deaths in a population numbering only 10,000. After this date the numbers slowly diminished. I have dwelt thus in detail on the epidemic in Ashkhabad, partly because of the importance of the town, but chiefly from the interesting fact that the disease remained there in insignificant proportions for several weeks and only assumed a severe aspect after extremely hot and stagnant weather.

north is derived from the distillation of sea-water. It need scarcely be said that in this province there is no system of drainage. Throughout the Central Asiatic provinces there exist the so-called 'Persian' or 'dead wells', which receive all excreta. These are deep pits or wells, often as much as eight sajenes (fifty-six feet) in depth. Besides these deep holes human excrement in no case remains on the surface of the earth, as in accordance with the local customs it is dug into the soil as soon as possible.

Having traced the disease westward to the shores of the Caspian I may turn and briefly review its course eastward. On June 8th a conductor of one of the trains was taken

* The influence of these figures may be best appreciated by supposing that the same proportion to population had been observed in St. Petersburg. In that case we should have heard of 500 cases in one day with 1600 deaths.

* Report of the Medical Department of the Ministry of the Interior for the year 1892. St. Petersburg 1891.

ill on the train and removed at Bokhara Station, where he died next day, and about the same time two privates of the railway battalion of troops died at the same station. The town of Bokhara lies fifteen versts (ten miles) from the railway station, round which, however, has grown up a small Russian settlement. From the Khanate capital no official figures have been published either of cases or deaths. It is possible that there were no cases there, if this be so it is a high tribute to the radical measures of sanitation carried out last winter at the instance of M. Lessar, the Russian diplomatic resident in Bokhara. From Merv equally no official figures have appeared, though at the time of the excessive mortality in Ashkhabad it was stated that there was also a considerable number of cases in Merv. One of the earliest places to be affected in Russian Turkestan (generally spoken of as the Turkestan border) was Dyzak, between Samarcand and Tashkent. Cases occurred there as early as May 31st, and from this date till June 20th there were in all 356 deaths from cholera. Samarcand escaped lightly, from May 31st till July 16th—when reports from there ceased—there were 148 cases with 88 deaths. This comparative immunity it probably owes—at least, in part—to its high position on the banks of the Zerashan river. From Samarcand the infection spread eastward and reached Tchinaz on June 5th. Tchinaz is a town on the left or western bank of the Syr Daria river, and there is here a ferry which carries the traffic between Samarcand and Tashkent. In this last-named town, the capital of Russian Turkestan, the first cases were reported on June 11th. Tashkent was much more severely affected than Samarcand, from the beginning of the epidemic till Aug. 20th, when reports ceased, there were 1058 deaths from cholera.

A word as to the inhabitants of these provinces may not be out of place here. In the Report of the Medical Department of the Ministry of the Interior for 1887 (published in 1889) some interesting details are given as to the tribes in the regions of the Amu Daria. The chief tribes are the Turkomans, the Sarts, the Karakalpaks and the Uzbeks. The Turkomans live in *auls*, in dome-shaped *kibitkas* or huts built of rushes or twigs, each *kibitka* is in the centre of a court or yard surrounded by a clay or mud wall. These courts are said by the report to be "evil smelling, to abound in excrement and filth, as the Turkomans do not remove their refuse on to the fields, there is no vegetation in the *auls*, water is taken from the *ariks*, or artificial irrigation channels, or from lakes, it is, of course, dirty, as the cattle drink from and bathe in it. At the end of the summer there is very little water left in either the *ariks* or lakes, the people suffer from want of water, but do not dig wells." The reason why they do not dig wells is probably to be found in the fact that water in the wells, whether deep or superficial, is always either salt from the first or very soon becomes so. The Sarts are more inclined to commerce than the Turkomans, and "always live near the towns and bazaars and adapt themselves to the local customs of the inhabitants." The Karakalpaks "live on the banks of rivers in *kibitkas* summer and winter, and are so hardy that even with 20° of frost Réaumur (-13° F) they do not complain of the cold or wish to change their tent life. During the time of the inundations of spring and autumn they move their tents to the highest-lying land and live as on islands, constantly occupied in catching fish, on which they live and in which they trade. In consequence of this mode of life they suffer from intermittent fever, rheumatism and leprosy." The Uzbeks, a more settled race, live constantly in the same place in *saklia* or huts, close to broad *ariks*, and occupy themselves with agriculture. "Their huts are built of clay, are six to seven arshins (fourteen to sixteen feet) in height, with an opening in the roof for escape of smoke, there is a hearth in the centre of the hut, where the fuel is the knotty *saxaul* wood. About the hearth are spread mats or among the rich, carpets, and near it is a hole or ditch into which slops are thrown, and which is not unfrequently soiled by the dejecta of the children. Beds are only found among the well-to-do, and generally the Uzbeks sleep on the mats side by side, without distinction of sex. The foul smells, the flies and mosquitoes, the high temperature in summer and the cold in winter make a *saklia* not only an unpleasant but also a dangerous habitation. The excreta and refuse are heaped together round the houses, mixed with sand which contains a quantity of lime, and in the spring removed on to the fields as manure. Each *saklia* has a garden and rice plantation, which require abundant watering. The prevailing diseases among the Uzbeks are intermittent fever, trachoma, gastro-intestinal catarrh and cutaneous diseases." The occurrence

of the last may not be unconnected with the personal habits of these people, who, like the Caucasian highlanders, change their linen only once a year, on the Feast of Bairam! In summer the children suffer greatly from choleraic diarrhoea and dysentery, and the mortality is very high. Very many families are the subjects of syphilis. Amongst a population of this nature it is not surprising that the epidemic of cholera was severe, as shown not only by the numbers attacked but also by the percentage of fatal cases. From the table to be given in the next article it will be seen that the proportion of cases to the population was very markedly higher in the provinces of Turkestan than in any other district in Central Asia. In Ferghana (the former Khanate of Khokand), out of every 100 000 inhabitants 2415 suffered from the disease, and in the province of Samarcand out of the same number 2138 were attacked, figures representing a sufficiently severe visitation, and only exceeded in the present year in certain districts of the Caucasus and in the government of Astrakhan. Tracing the further course of the epidemic to the more northerly districts of Central Asia and Siberia, it appears that the province of Uralsk was first affected early in July. This province lies to the north of the region between the Caspian and Aral Seas. The first cases occurred on July 8th amongst the Kirghiz inhabitants of the town of Gurief at the mouth of the Ural river. The province suffered somewhat severely, the proportion of cases and deaths per 100,000 inhabitants being 1023 and 524 respectively.

(To be concluded.)

SOME REMARKS ON THE PATHOLOGY AND TREATMENT OF TYPHOID FEVER

By P W LATHAM, M D CAMB, F R C P LOND,
SENIOR PHYSICIAN TO ADDENBROOKES HOSPITAL, AND DOWNING
PROFESSOR OF MEDICINE IN THE UNIVERSITY OF CAMBRIDGE

AND

ARTHUR C LATHAM, B A,
BALLIOL COLLEGE, OXFORD

(Concluded from p 466.)

PART II

ON THE TREATMENT OF TYPHOID FEVER

By P W Latham.

WE come now to consider what are the indications for treatment which result from these investigations. First, if the patient comes under observation at an early period of the disease—that is during the first eight or ten days—obviously the points to aim at would be to eliminate as many as possible of the bacilli from the intestine, to paralyse or attenuate such as remain and to eliminate or neutralise the toxic material from the economy, if these objects can be attained the result would be either to cut short the disease or to abridge its future course and render it milder. In a great proportion of cases diarrhoea sets in early, but in some there is obstinate constipation, and the most severe cases I have seen have been those in which for two or three or four days at the commencement of the disorder no action of the bowels has taken place. From what has been previously stated this is quite intelligible. If diarrhoea exists, some portion of the toxic material generated by the bacillus is swept out of the body, together with numbers of the bacilli themselves. If, however, the bowels are confined, the whole of the toxic material is absorbed into the system, producing its deleterious effects, as shown by rapid rise of temperature &c., the bacilli themselves increasing at the same time rapidly in number. The indication, then, at this stage is to eliminate the toxic material from the intestines by acting upon the bowels and using such antiseptic remedies as will powerfully affect the bacilli.

Now amongst intestinal antiseptics calomel is probably the best. It materially retards decomposition due to low organisms and its antiseptic power is not as greatly diminished by admixture with fecal matters as is that of other antiseptics. From its insolubility it passes into the intestines and so comes in direct contact with the parts where its action is most needed, putting a stop to the growth of the bacilli or attenuating their virulence. Here it may be remarked that it is

no new thing to advocate the use of calomel in typhoid fever. Dr. Anthony Todd Thompson used to give it, Dr. Parkes considered it was to be strongly recommended in this disorder, given not later than the tenth or eleventh day and at no time in large doses—one or two grains twice a day was enough. Wunderlich prescribed one to five grains twice daily, which Dr. Parkes considered too large a dose. Sir William Aitken writes: "In the great majority of cases where it can be given during the first week and before the occurrence of much diarrhoea the course of the disease is rendered milder and shorter." But these high authorities gave it in order "to influence the elimination from the intestinal glands by direct local action on the intestinal membrane." The late Dr. George B. Wood of Philadelphia, in his "Practice of Medicine," bears testimony to the benefit to be derived from mercury about the seventh or ninth day of the fever, and he held that "it tends in some degree to arrest the progress of the disease in the glands of Peyer and to promote resolution of the inflamed patches." What I suggest is that it acts beneficially by attenuating or arresting the development of the typhoid and other bacilli (*Bienstock's bacillus*, *bacterium coli commune* &c.) in the intestines, and so removing the cause of the disease. The toxins of these bacilli have already been absorbed into the blood stream, but they will soon be eliminated or possibly in some way, as yet not clearly made out, rendered innocuous if the further supply of them be cut off. By cutting short the disease I do not mean that the patient passes at once from a state of disease to that of health. That is impossible. But what I do mean is that the specific process—the development, that is, of the specific poison—is put a stop to. The swelling of the intestinal glands, the congestion of the intestinal mucous membrane, and the swelling of the mesenteric glands associated with this specific poison have taken place, and, though the specific disease is cut short, these morbid conditions, which by themselves would give rise to pyrexia, diarrhoea &c., require some days before they pass away and the parts regain their normal states. It takes some days after the disease is cut short to repair the damage done by the poison.

If, then, a patient comes under observation during the first week, and there is no diarrhoea, I would recommend the administration of five grains of calomel, the dose to be repeated the following day if not more than two copious evacuations are produced by the first dose. If there be slight diarrhoea, a quarter of a grain, or half a grain, or a grain of opium may be added—just sufficient to check excessive peristaltic action. If the opium stops this action altogether it will do harm. If diarrhoea is a marked symptom at the commencement of the disorder, or if violent meteorism, albuminuria or great anæmia exists I should discard the calomel and use one or other of the remedies to be referred to directly. Where calomel acts beneficially the temperature is reduced, the beneficial remission is persistent, and a considerable shortening of the whole febrile period takes place. The cases in which it has seemed to me to act most satisfactorily have been those in which its administration about the sixth or seventh day has been followed by three or four copious greenish evacuations, a lowering of the evening temperature from 104° or 104.5° to 103°, and subsequently from the eleventh or twelfth day the evening temperature gradually declining until about the nineteenth or twentieth day it reaches a normal point. Liebermeister gave three or four ten grain doses in the early stages of the disease, and was satisfied that he caused the attack to abort in a number of cases. I have never given such large doses. Further experience, however, may show their utility and indicate the conditions in which they may be safely employed. Still it appears to me that when by the sixth or seventh day the evening temperature has reached 104° or 105° the damage done is so great that, though the typhoid bacilli are destroyed and the specific disease is cut short yet, for the reasons I have already given, the patient's evening temperature will not reach the normal point earlier than the nineteenth or twentieth day. After giving one or two five grain doses of calomel, the remedy may be given on subsequent days in smaller quantities—one or two grains once or twice a day in combination with opium and ipecacuanha, endeavouring to adjust the quantity of opium so that there should be one, two and certainly not more than three evacuations daily and suspending the use of the opium at once if it paralyzes the peristaltic movement of the bowels and leads to increased tympanites. Or the following may be employed from three to five grains of mercury with chalk, two grains of compound ipecacuanha

powder, with a sufficient quantity of confection of roses as pills, or three grains of blue pill may be substituted for the grey powder.

With regard to the effects of mercury in the treatment of continued fever, it must be borne in mind that in this disorder the gums do not readily take on the mercurial action. This specific action must, however, be carefully looked for, and when symptoms of mercurialism appear the remedy must be suspended or given at longer intervals. As soon also as the evening temperature of the patient shows continuous daily remissions I should suspend the remedy or lessen the dose, according to circumstances. Upwards of fifty years ago Dr. Peter Mere Latham compared the mercurial treatment with different modes of practice in different cases of the same epidemic. "Finding one season that his wards were full of fever, whilst yet its type was so mild that scarcely any died, he thought this a favourable opportunity for trying whether mercury had any beneficial operation upon the disease. Accordingly he treated half his cases with small doses of mercury with chalk and the other half with the liquor ammoniæ acetatis and so forth, and no mercury, and he found that the patients in the first of these classes were on the average, convalescent sooner than those in the last."

Ipecacuanha is a very useful addition to the mercury, as in small doses it retards the peristaltic action of the intestines and lessens the secretion from the mucous membrane. It may do more than this: the beneficial action of large doses in dysentery is very striking and has not as yet been explained. I am not at present prepared to express an opinion upon what was once the favourite practice with physicians, of giving an emetic of ipecacuanha at the onset of a fever. The mode of action of this drug in large doses, independently of its emetic action, requires further investigation. Sir Thomas Watson, in discussing the treatment of fever, says "Perhaps emetics may, in the present day be too much neglected. I have no notion of their stopping the fever, but when given early, especially if gastric disturbance be a prominent symptom, they are sometimes followed by a marked abatement of many morbid sensations." "It is astonishing," says the observant Sydenham, "how it happens that a vomit which does not produce either a large or a morbid discharge from the stomach should so materially relieve the nausea, restlessness, anxiety and furred tongue of the patient."

After the end of the second week of the disease constipation is to be carefully guarded against. The late Dr. Todd wrote "Restrain diarrhoea and hæmorrhage in typhoid fever, and when you have fairly locked up the bowels keep them so for four or six days or even longer." To carry out the latter suggestion is, I think, most prejudicial—and for two reasons. In the first place there is allowed a greater absorption of the toxins from the alimentary canal and it will generally be found that with constipation the temperature of the patient rises, in the second place, by allowing an accumulation of fæces, especially in the lower part of the ileum, the risk of perforation taking place is very materially increased, the intestine is put on the stretch, and if there be a deep ulcer the peritoneal covering may give way. In some animals, it will be recollected, it was only after the intestinal peristaltic action had been stopped that Sætz succeeded in producing typhoid fever. I think it best where there is a tendency to constipation to secure at least one daily evacuation, and, if by means of small doses of calomel or grey powder this is not effected, then to administer daily an enema of about half a pint of soap-and-water.

If there be too copious or excessive diarrhoea this must be restrained, and the best remedies are the subnitrate of bismuth and tannic acid. The subnitrate of bismuth acts beneficially in two ways: first of all it is a good antiseptic when brought in contact with the surface of substances—as is seen by its preventing any offensive discharge when sprinkled over fresh wounds. Owing to its insolubility it exerts little antiseptic effect when added to liquids. Its antiseptic effect may be due in some measure to its slowly giving off nitric acid, which is an energetic bactericide, but it possesses also another special action in intestinal mischief. It was found by Gosselin and Heret² from experiments made on rabbits that the action of sulphuretted hydrogen in the intestines gives rise to violent peristalsis. If then, this gas as the result of the putrefactive changes is present in excessive quantity in the intestines on administering a salt of bismuth the gas is readily absorbed by its forming sulphide of bismuth, and so

¹ See Kocher, Volkmann's Klinische Vorträge No. 224.

² Centralblatt für die Medicinische Wissenschaft, 1886 p. 574.

the increased peristalsis subsides. The subnitrate when pure has no irritant property and can be administered internally in very large quantities without injury, though when applied in large quantities to external wounds so much may be absorbed as to cause poisoning, characterised by acute stomatitis, followed by intestinal catarrh &c. The liquor bismuthi et ammoniæ citras is also undoubtedly capable of acting as a violent gastro-intestinal irritant. In typhoid fever, therefore, the insoluble subnitrate alone should be used in doses of fifteen, twenty or thirty grains three or four times a day or oftener, according to circumstances. In tuberculous diarrhoea much larger doses are often given with the happiest results. Monneret gave as much in these cases as an ounce during the day. He says "In the last seven years during which I have administered the medicine in tuberculous diarrhoea, I have seen many persons who appeared to have but a few days to live cured of their diarrhoea, so far as to be able to take food, gain flesh and strength and leave the hospital under an impression that they were cured."³ In the diarrhoea of children who are being weaned or are fed artificially this remedy acts very satisfactorily, and the explanation of its action in all these cases must be sought for in its bactericidal properties.

As stated in the first part of this paper, the addition of subnitrate of bismuth to various media seems not to stop the growth of the typhoid bacillus. It grows in them just as readily as in media to which 0.25 per cent of carbolic acid has been added. It may be that the bismuth diminishes the virulence of the bacterium coli commune, the products of which, as has been already pointed out, may prepare the soil for the typhoid bacillus. This is a point on which further investigations are necessary and will be made. Of course it is very necessary in giving the remedy in large doses, especially in typhoid fever, to be quite certain that it contains no arsenic, an impurity which unfortunately exists in many specimens. Reinsch's test furnishes a rapid means for doing this.

In tannic acid also we have a useful remedy in the diarrhoea of typhoid fever. It has no effect on the peristaltic movement of the bowels, but it diminishes the secretion from the glands, renders the faeces more consistent and in large doses destroys the peculiar faecal odour. It possesses bactericidal properties and so checks putrefaction and removes unpleasant odours, but it is inferior in these respects to other agents, as strong solutions are necessary for the purpose. It may be given (best as pills) in doses of from three to five grains twice or three times a day—alternately, if necessary, with the subnitrate of bismuth, if there be excessive diarrhoea and tympanites. Where the latter is a prominent symptom at the end of the second or beginning of the third week of the disorder the use of oil of turpentine is sometimes very serviceable. Not only does it lessen secretion from mucous membranes,⁴ but it puts a stop to putrefactive and fermentative processes. This may be due to the turpentine ($C_{10}H_{16}$) itself, but the bactericidal properties are intensified by the peroxide of hydrogen and the ozone, which the oil, after exposure to air and light, is found to contain. The late Dr. George B. Wood of Philadelphia, Dr. Graves and Dr. Murchison have recommended this remedy. Dr. H. C. Wood says "There are two conditions or stages in which it is especially useful—indeed, is of incalculable service. About the end of the second week the tongue sometimes becomes very dry, red, chapped, perhaps coated in the centre with a brownish fur, and at the same time marked meteorism develops. Ten drops of turpentine every two hours during the day and every three hours during the night will in the majority of cases relieve the bad symptoms noted. When convalescence is protracted, when there is a constant tendency to the recurrence of diarrhoea—when, in other words, the ulcers of Peyer's patches are slow to heal—turpentine acts almost as a specific."⁵ If albuminuria exists, however, the use of turpentine is contraindicated. Turpentine is also a most valuable remedy in intestinal hæmorrhage. John Hunter was one of the first to recommend its use. He says "I have seen it immediately stop vomiting of blood from the stomach when all other means had failed. It is the best if not the only styptic."

Another remedy which may be used with advantage in the second and later weeks of typhoid fever is β -naphthol. It is one of the most powerful antiseptic agents, possessing three times the strength of carbolic acid or iodoform and four times that of creosote and, being almost insoluble, is one

of the best agents for disinfection of the intestines. When administered in typhoid fever it deodorises the stools, lessens the tympanites and renders the tongue moist. It may be given in doses of from three to five grains every two, four or six hours, according to circumstance. If there be profuse diarrhoea it may be given alternately with subnitrate of bismuth.

Solution of chlorine is said to act beneficially when administered in this disorder, and its use has recently been strongly recommended by Boyd.⁶ Sir Thomas Watson says "For some time past I have been in the habit of giving to all my fever patients a drachm of the chlorate of potash dissolved in a pint of water as a daily drink. Without being able to tell you precisely in what respect, in what degree, or in what way this salt appears to do good, my own impression is strong that it does exercise some favourable influence upon the general character and course of the disorder." I suggest that the beneficial effect is due to the decomposition of the salt, chlorine and peroxide of chlorine being liberated, and to promote this decomposition I recommend the addition of one drachm of dilute hydrochloric acid to be added to the solution.⁷ This remedy may be used alone or in conjunction with small doses of calomel, but not with any of the other remedies referred to in this paper.

As regards antipyretics, such as phenacetin, antipyrin &c., my experience does not allow me to place much reliance upon their use. Occasionally a single dose or two have appeared to act beneficially, but in most cases the reduction of temperature has soon been followed by a rise to a higher point than before. In fact, the remedy seems to be directed only against one particular symptom, and though the body heat is temporarily reduced the typhoid poison, toxins or what not, which causes this symptom is, all the while, accumulating in the blood, and produces its full effect in spite of the remedy. The hyperpyrexia must, however, be controlled, and cold sponging and the cold bath are, in my opinion, the most reliable means for doing so. Possibly during the reduction of the temperature some portion of the typhoid poison may be eliminated through the kidneys or the skin and the condition of the patient improved. It seems to me that what we are most in want of just now is a remedy which will either promote the elimination of the typhoid poison from the blood through the usual channels or act as an antidote when injected into the blood. Possibly the serum of immune animals may be shown to have those effects, at all events, the results of experiments made in this direction, alike with regard to typhoid fever, to diphtheria and to tetanus, would lead us to hope that most important therapeutic agents are about to be brought into service for the treatment of these disorders.

Lastly, a few words as to diet and stimulants. In my opinion the best food of all in typhoid fever is milk diluted with water, the dilution being carried only so far that no curd or undigested milk is to be seen in the evacuations. Five ounces of milk with one or two of water may be given every two hours. To feed a patient oftener, unless there are special circumstances, is injudicious. A larger quantity of milk may be given if the patient seems to require it and if he can digest it. If necessary, the milk may be peptonised, perhaps in the later stages of the disease this may be called for, but in the earlier stages it is generally unnecessary. Soups and beef tea are frequently given, but they are much less nutritious than milk, and not unfrequently they tend to increase the diarrhoea. Now, though the typhoid bacillus can be cultivated in milk,⁸ other intestinal bacilli do not appear to thrive upon it, and in individuals fed exclusively on milk—children, for instance, at the breast—the faeces contain only the bacterium coli commune. Biernstock's bacillus, the bacillus putrificus coli, appears only when other kinds of animal diet are taken. A milk diet also, as it produces no irritating effects on the intestinal tract, may contribute less towards increasing the virulence of the bacterium coli commune than animal soups &c., and perhaps herein lies the explanation of why the latter may be provocative of diarrhoea. This, also, may perhaps explain the reason why relapses are so readily brought about in cases of typhoid fever by the too early administration of solid or semi-solid animal food. Imperfectly digested, it may irritate the alimentary canal, and either the altered secretions or the undigested food itself may furnish material for increasing the virulence of the bacterium coli.

⁷ The decomposition is as follows $4\text{KClO}_3 + 12\text{HCl} = 4\text{KCl} + 6\text{H}_2\text{O} + 3\text{ClO}_2 + \text{Cl}_2$.

⁸ Wolfhügel and Biedel, loc. cit.

commune, the toxins of which then prepare the soil for reviving the attenuated and enfeebled typhoid bacilli, which are even at this time still tenacious of the intestinal glands.⁹ As regards the administration of alcohol in typhoid fever, it is unquestionable that many cases do extremely well without its aid, and unless its use is clearly indicated patients are better without it. Alcohol is clearly indicated when there is prostration, with a feeble and soft pulse, the extremities cold, the tongue dry and brown, if there be stupor or low delirium, and especially if the impulse of the heart's apex is diminished and the first sound of the heart is feeble. Then a small dose of wine or spirit should be administered, the result watched, and the dose increased, diminished or discontinued according to its effect. Long ago the following rules were laid down by Dr. Armstrong, and endorsed by Dr. Graves, as to the propriety of persevering in the administering of wine in fever, and no better ones can be framed: "1. If the tongue becomes more dry and brown it does harm, if it becomes moist it does good. 2. If the pulse become quicker it does harm, if it be rendered slower it does good. 3. If the skin become hot and parched it does harm, if it become more comfortably moist it does good. 4. If the breathing become more hurried it does harm, if it become more deep and slow it does good. 5. If the patient become more and more restless it does harm, if he become more and more tranquil it does good."

Such, then, are some of the remedies that appear to be useful in the treatment of typhoid fever. They are nearly all old remedies—empirical—their use suggested by the keen clinical observation and experience of the physicians of a bygone age. The scientific investigations of the present day are now teaching us how to employ these same remedies with greater precision.

THE PHYSIOLOGY OF DEATH FROM TRAUMATIC FEVER

A STUDY IN ABDOMINAL SURGERY

By JOHN D. MALCOLM, M.B., C.M., F.R.C.S. EDIN.,
SURGEON TO THE SAJJARITAN FREE HOSPITAL.

(Concluded from page 462.)

The effect of the contraction of the vessels on the blood.—The effect on the blood itself of the existence of the febrile condition is great, and certain experimental and clinical facts are of importance as aids to our comprehension of the results produced. Constant interchanges go on between the fluids in the tissues and those in the bloodvessels, and also between the former and the contents of the lymphatics, whilst the lymphatic system also communicates directly with the venous system. When a shrinkage of the vascular capacity occurs, there must necessarily be a diminution of the amount of blood in the vessels, and the fluids of the body must therefore accumulate in increasing quantities in the tissues and lymphatics. Hence, when the arteries contract in inflammation, in the absence of venous congestion, there must be much tension induced within the tissues throughout the body. In a favourable case this tension is physiologically relieved by the action of the excretory glands and especially of the sweat glands. It is to be noted that an extreme contraction of the arteries or even the shutting off of the blood supply altogether, will not prevent the action of these latter glands.¹ Sweating indirectly removes much of the blood plasma. There is no evidence, however, that the blood corpuscles are carried off in this way. If only the plasma were got rid of, a very great increase of the number of red blood corpuscles relatively to the liquor sanguinis would result. This, however, is not found to be the case. Dr. Lockhart Gibson has recorded that "the white corpuscles always rise in number and the red corpuscles always fall in number for a day or two after operations and that without any regular proportion to the amount of blood lost."² The red blood corpuscles must therefore be eliminated in some way. In health these corpuscles are continually being broken up and are as steadily being formed, but the rate of formation and destruction varies. The changes are

greater in youth than in old age and are very active after food has been taken.³ During the febrile process also there is evidence that the red blood corpuscles are destroyed in great numbers. The amount of this destruction at any time may be estimated by the amount of bile pigments formed.⁴ That there is not usually any very obvious sign of an excess of bile formation in an ordinary case of traumatic fever is no proof that such does not take place. "Normally a great part of the bile goes round in a circle from the liver into the duodenum, thence into the blood, so to the liver again, whilst another part is carried down by the contents of the intestine, and after becoming more or less altered passes out of the body with the feces."⁵ There are therefore no clinical means of measuring the bile formation, although bile sometimes passes in the stools in obviously excessive quantity during a fever. There can be no doubt, however, that an increased formation of bile or of certain constituents of it does occur during the febrile state. It has been shown that the formation of bile and of urea depends in large measure on the destruction of red blood corpuscles, and that these excretions are therefore necessarily increased or diminished together.⁶ In fever the urea excretion is greatly increased, and the urine pigment derived from the hæmoglobin may be augmented twenty times.⁷ There is therefore distinct evidence of increased destruction of blood corpuscles during the febrile process. Again, in cases of obstruction of the intestine or of pseudo-ileus after laparotomy, along with the increasing contraction of bloodvessels, there is marked evidence of great destruction of blood corpuscles before the secondary rise of temperature takes place. There is very evident diminution in the amount of excretion by the kidneys, amounting to complete suppression before death, but there is invariably a great and increasing quantity of indican in the urine which may be observed before any signs of suppression are detected. The amount of pigment vomited is also very great, whilst after death the liver is dark coloured and the gall bladder is distended with black bile. This altered bile is certainly produced in very large quantity, and it must be concluded that there is a correspondingly great destruction of red blood corpuscles. It is further to be borne in mind that this excessive destruction of blood corpuscles is in these cases of pseudo-ileus, contemporaneous with the contraction of the arteries and not with an increase of temperature. On the contrary, the temperature, sometimes at least, is falling when the vomiting of altered bile is becoming excessive. In shock nothing is known, so far as I am aware, of any effects of the condition on the amount of bile and urea excreted, but convalescence from shock is often preceded by bilious vomiting which may be due to increased secretion of bile and other fluids. With the certainty that the blood plasma is diminished, there is thus a considerable amount of evidence that the red corpuscles are also destroyed and excreted in conditions in which great contraction of the arteries occurs. According to Dr. William Hunter we should expect to find the plasma and corpuscles of the blood thus removed, if at all, in their normal proportions. He has shown that the most remarkable feature presented by the blood is the "power it possesses of maintaining a composition as rightly entitled to be termed stable as that of any other tissue of the body."⁸ During health the destruction of blood corpuscles is accompanied by a corresponding amount of blood formation, so that the blood remains nearly or quite constant in quality and quantity. Hence increased formation of blood would seem to be a physiological consequence of excessive destruction of it. But, whilst the capacity of the vascular system remains small or is being reduced increased blood formation can only lead to still greater blood destruction. The formation of such a complex entity as a blood corpuscle must, however, make great demands on the supplies of nutriment, and therefore any great increase in the activity of blood formation is quite sufficient to account for the extreme wasting of the fatty tissues and skeletal muscles which undoubtedly takes place during fever.

The temperature in traumatic fever.—I now turn to the consideration of the temperature in fever. There cannot be any doubt that the contraction of the arteries to which I have endeavoured

voured to trace so many of the symptoms which are observed in fever may exist in a very marked degree without any elevation of temperature being found. Moreover, great disintegration of the blood may occur when the temperature is falling. It has also been pointed out by Burdon Sanderson that "the febrile augmentation of the urea discharge takes place immediately after subcutaneous injection of pus—i.e., at a time which precedes the elevation of temperature."⁹ It is therefore certain that an excessive destruction of red corpuscles may take place when there is no elevation of temperature, and consequently that the elevation of temperature in traumatic fever does not depend on the increased destruction of blood corpuscles. In seeking for the cause of the elevation of temperature in fever, whilst attributing the excess of excretion of bile, urea and the like products to the unusually active destruction of blood corpuscles necessitated by the advancing contraction of the arteries, it might be suggested that the rise of temperature is coincident with, and caused by, the compensatory increase of blood formation. But "the urea discharge remains"¹⁰ excessive during the whole course of the fever. Therefore an excessive destruction of blood must go on also during the whole process. The patient, however, towards the end of an uncomplicated traumatic fever is evidently gaining strength and blood. At this time, not only must the blood be formed to replace that which is being destroyed, but, as the vessels relax, the increasing intra vascular space must also be filled up. Hence increased blood formation must continue, if indeed it does not become more active, as resolution progresses. The temperature is, however, falling during this time and therefore increased blood formation cannot be the cause of its elevation. Nevertheless, the formation of blood corpuscles in unusual numbers must involve a large amount of tissue change in many parts of the organism. Calorimetric experimental evidence shows that whilst these processes of excessive blood formation and blood destruction and the wasting of the tissues and their subsequent return to the normal are going on there is an increased elimination of heat. The variations in the amount of heat production and heat elimination which take place in health are very great. The taking of food and starvation, active exercise and repose, the temperature of the surroundings and other conditions have a marked effect on the amount of heat developed and eliminated. In health these conditions have little or no influence on the body temperature. Elevation of temperature, therefore, does not depend on increased production of heat. In fact, less heat is produced in fever on fever diet than in health on full diet.¹¹ It has been shown that an elevation of temperature may be brought about by a stimulation of a portion of the brain substance to the "mesial side of the corpus striatum near the nodus cursorius of Nothnagel."¹² The conclusion has been drawn that by the stimulation of a particular nerve area in the situation named "the thermogenetic function of the muscles is abnormally increased."¹³ But, if an elevation of body temperature does not depend on an increased production of heat, then no such simple explanation of the thermogenetic, or rather heat raising effect thus produced is satisfactory. A more rational view of the thermal phenomena of fever is that elevation of temperature depends in no way on increased production of heat, but on something which disturbs the arrangement whereby heat production is counterbalanced by heat elimination. This undoubtedly sometimes occurs, and there can be little doubt that the mere stimulation of a thermogenetic tract will not cause a rise of body temperature so long as the rest of the heat-regulating mechanism remains intact. With this mechanism in a healthy condition an extra development of heat would at once produce compensating thermolysis, as when food is taken and after violent exercise, therefore thermolysis must be interfered with at the same time that thermogenesis is stimulated, or the temperature will not rise.

Every assumption that the muscles are in a special manner the heat producing tissues, that they have a thermogenetic function peculiar to themselves, and that on the excessive exercise of this function the febrile condition depends, seems to me open to objection. Doubtless the changes which take place in fever and which lead to marked wasting of the muscles, are associated with the development of heat in the

muscles and are not dependent on, nor associated with, the exercise of the contractile function of their tissue. I have, however, shown that there is some reason to suppose that the wasting of the muscular and fatty tissues during the febrile process may be secondary to the efforts made by the organism to supply fresh blood in place of that which is destroyed. It might be argued from this that the blood forming organs have the greatest claim to be described as specially fever producing. We have, however, seen that the blood forming function is also very active when fever is abating. A special claim to the title of thermogenetic cannot be established for any tissue. Probably all the tissues are thermogenetic in proportion to their bulk and vascularity. An explanation, which I believe to be new, of the rise of temperature in traumatic fever has suggested itself to me. It has been shown, as already pointed out in this paper, that whilst the inflammatory process exists there is in the affected part a temporary partial devitalisation of tissue which is the primary lesion of inflammatory congestion.¹⁴ There is also evidence that during the advance of an inflammation an increasing area is subjected to this condition of diminished vital activity. I have endeavoured to show that this local condition, although the parts are full of more or less stagnant blood and are surrounded by a very active circulation, may transmit to the vaso motor centre an indication that there is a want of fresh blood in the part. Exactly in the same way, it seems to me that, although the parts are surrounded by an active circulation of blood which is above the normal body temperature, and though they are themselves actually above that temperature, yet, in the process of dying or becoming partially devitalised, as the normal local chemical reactions cease, the nerves of the affected tissues must transmit to the central nervous system an indication of increasing physiological inactivity—of the approach of the coldness of death. This would be expected reflexly to stimulate heat production, but if the body temperature be raised those tissues which eliminate heat—notably the skin—will be excited to increased action. Thus the local condition tends to raise the temperature whilst the heat regulating mechanism endeavours to bring it down to the normal, and on the comparative power of these opposing forces depends the result at any particular moment. It is to be noted that, though I have attributed the changes in the pulse and in the temperature to separate physiological mechanisms, they are traced to the same cause—the partial devitalisation of the inflamed tissue, hence, in the condition of simple fever the pulse and temperature rise and fall together, but this correlation may be altered by various complications.

The specific fevers—The foregoing conclusions apply to the simplest forms of fever only. It seems to me, however, that in every fever all the conditions which I have described may be detected. In the specific fevers and in the septic fevers there is evidence that some processes are taking place besides and beyond those which constitute a simple fever arising from an injury. The superadded causal condition is a specific poison giving rise to the pathognomonic signs of the particular disease produced. Of the fevers thus brought about the septic varieties are specially deserving the attention of the surgeon. By septic fever and by septicæmia I mean a complication of traumatic fever due to the absorption of a poison through a wound. The admission of a poison through a mucous membrane, as described by Olshausen and Verchère, has been regarded by some as a mode of development of septicæmia. I have endeavoured to show that in the case instanced death is due to other causes. Cases may occur, however, in which a poison which requires no wound for its entrance gains access to the tissues of a patient who has been operated on. It is believed, for instance, that operation cases and recently delivered women are specially susceptible to the poison of scarlet fever. All such cases should, if possible, be clearly separated from those of surgical septicæmia. Such an essential difference in etiology forbids that they should be classed together. The clinical symptoms and post-mortem signs of a septicæmia are those of a universal irritation added to those of a traumatic fever. Except in cases of septic intoxication, micro-organisms have been found in all the tissues of the body, but of all the organs the kidneys are most constantly affected in this way,¹⁵ and clinical evidence is very strong that through the renal tissue the elimination of the poison is mainly effected. In all forms of the disease if, and so

long as the kidneys continue to act there is a possibility even a probability, that the patient may recover, but if albuminuria and suppression of urine occur, and are at all continuous, death will speedily follow. We cannot, however, attribute death from septicæmia with suppression of urine after an operation to retention of physiological effete matter which ought to be excreted. As I pointed out in regard to obstruction of the bowels after an operation, so in this case death is too rapid to be due to the complication alone. Septicæmic suppression of urine rarely lasts more than three days, whereas in simple obstructive suppression of urine life is usually prolonged for from nine to eleven days.¹⁶ Septicæmic suppression of urine leads, however, to great interference with the circulation of the blood through the kidneys, and thence arises a physiological condition in every respect parallel to that which exists when the blood flow through the mesenteric vessels is interfered with by intestinal distension in cases of obstruction or paralysis of the bowel after laparotomy. It seems to me that death is induced in exactly the same way in both these conditions. There are, therefore, many resemblances between the two classes of cases but the only common cause of the exacerbation of the inflammatory fever in septicæmia and in pseudo-ileus is the obstruction to the flow of blood through a large and important vascular area. So like, however are the two modes of death that Olshausen and Verchère, though recognising that there is a difference, have attributed the symptoms of pseudo-ileus to a species of septicæmia peculiar to itself. It may be stated generally that any complication which raises the blood pressure during a traumatic fever is dangerous, and if persistent may induce death in the manner which I have described. Those who do not attribute the changes caused by even the simplest fever to peripheral irritation assert that the phenomena observed are always due to the formation of some poisonous substance, which, circulating in the system, induces the febrile condition. If it be assumed that peripheral irritation is not the cause of fever, both the hypothetical substance which produces this disturbance and its mode of action have yet to be discovered. On the other hand, the views of traumatic fever which I have endeavoured to formulate explain also how certain irritant poisons may cause all the characteristic phenomena of the febrile state. Circulating in the system, these poisons must give rise to a widespread irritation and consequent partial devitalisation of tissue. Such a widespread partial devitalisation of tissue must produce the same effects on the vascular and thermal systems as are brought about by the more obvious devitalisation due to a local irritation. The effect may be slight or so severe as to induce great contraction of the vessels, a high temperature and death. It is even conceivable that death may be produced almost with the suddenness of shock. In accordance with this we know that in scarlet fever for example, a fatal result is sometimes brought about before any pathognomonic signs of the disease show themselves. Cholera and certain snake poisons may also kill with extreme rapidity. The peculiarities of the poison, of the individual and of the tissues fully account for the conditions found in the special diseases produced. In every febrile disease there is evidence of peripheral mischief. Sæpiæmia, septicæmia, pyæmia and all the exanthemata show signs of a widespread irritation with a tendency to inflammation in certain tissues and organs.

FRANKLIN STREET, W.

A CASE OF REMOVAL OF A PORTION OF THE SIGMOID FLEXURE

By FREDERICK TREVES FRCS Eng,
SURGEON TO THE LONDON HOSPITAL.

Within the last few years surgical literature has become very exuberant in matters relating to the excision of intestine and the union of divided bowel. The long list of intestinal anastomoses has been considerably extended. To many of simple mind it would appear that if two segments of bowel have to be sewn together there is little need for a suitable needle and cotton and some elementary knowledge of sewing. At the present time, however, this plausible

view meets with rebuke, and it is sought to be shown that the union of bowel involves an intricate elaboration of sewing which is far beyond the well practised art of the seamstress. In what may be termed the complexity of minor invention the intestinal suture can now take its place with the pessar and the obstetric forceps. To those to whom even Bor's modification of Cox's suture would not appeal there are offered a number of mechanical adjuncts to the process of suturing which are brought forward by clamorous advocates. These include bone plates, gut plates, gut rings, tubes, intestinal bobbin, intestinal buttons and the like. Amongst these appliances Senn's original bone plate is as a Triton amongst minnows. Dr Senn's invention opened up a new, ingenious and possibly valuable departure in abdominal surgery. Of the many imitations which have followed in its wake the majority are unimportant. Of the value of the bone plate it would be, I imagine, as yet premature to speak. The intestinal clamp after a brief existence, has passed into the background. It was an instrument for which there was no need. For one of the earliest forms of the clamp I was myself responsible, and although many varieties of the instrument have been invented since that effort I am satisfied to think that my apparatus still remains by far the worst.

I have ventured to publish the following case in order to show that simple measures in uniting bowel may possibly be attended by success and that the older method of operating so severely condemned by the advocates of the newest gut plate or bobbin, is not of necessity followed by the death of the patient.

A married woman aged forty-four was sent to the London Hospital on Nov 27th, 1891, by Mr Holroyde of Chatham. She had had excellent health until the previous June, when she had an attack of intestinal obstruction. This followed the eating of a considerable quantity of maize and was marked by colic, vomiting, constipation and distension of the abdomen. The patient was well again in fourteen days. A second but milder attack followed in August, 1892, and a third and much severer one in September. Between the attacks the bowels had responded readily to enemata and aperients. The symptoms of obstruction had passed away before the patient came to the hospital. On admission she was noted to be of healthy appearance and to be well nourished. The abdomen was soft, pendulous and distended. A very considerable quantity of fecal matter was evidently lodged in the colon. There was no ascites, no tumour could be detected, a few coils of bowel became occasionally visible, there was no vomiting and rectal and vaginal examination revealed nothing worthy of note. The treatment consisted of rest, daily massage of the abdomen, the daily use of enemata and aperients and the observance of a carefully selected diet. By these means the abdomen soon regained its normal size, an enormous quantity of fecal matter was evacuated, the appetite was restored and the patient left the hospital in sixteen days (i.e., on Dec. 13th) expressing herself as feeling quite well. The diagnosis which I caused to be entered in the notes was "stricture of the large intestine either in the descending colon or sigmoid flexure." No idea of operative interference at this stage was entertained by the patient. The absence of any of the usual causes of a simple stricture of the bowel led me to suppose that the stricture was due to epithelioma. Nothing more was seen or heard of the patient—who had moved from Mr Holroyde's district—until Nov 15th, 1892, when she again entered the hospital. During the year which had elapsed the phenomena of the previous six months had been repeated and intensified. There had been increasing constipation, a more constant use of aperients and more frequent and more severe obstructive attacks. Vomiting was common, the appetite was poor, the patient was haggard and anæmic, had wasted considerably and had become very weak. The abdomen was now greatly distended with ascitic fluid and measured forty-two inches at the level of the umbilicus. Much pain was complained of and vomiting was frequent and troublesome. Aperients merely added to the patient's distress and enemata produced very little effect upon the now evidently much distended intestine. Rest and opium gave the patient relief and served to prepare her for the operation which was carried out on Nov 25th. There was at no time any albumen in the urine. The abdomen was opened through a median incision three inches in length. The ascitic fluid which escaped filled one full sized bucket. An nodular epibolemic growth was found on the summit of the

¹⁶ Dr Wm. Roberts: *Urinary and Rectal Diseases*, p. 72.

sigmoid flexure. It presented the usual simple ring, had formed no adhesions to adjacent parts and had not extended beyond the bowel. The abdomen having been freed of all ascitic fluid, the affected loop of bowel was drawn out of the wound and numerous sponges were wedged around it so as to make the operation in every respect extra abdominal. The growth was found to involve the colon for one inch and a half of its extent, no enlarged glands were detected, the bowel above the stricture was greatly hypertrophied and was so distended as to equal the adult forearm in circumference. The gut below the stricture was thin, empty and contracted. The colon above and below the part to be excised was clamped by the fingers of my house surgeon, Mr Speechly. Seven inches of the sigmoid flexure were then cut away with scissors. The contents of this segment were received upon a special sponge. The interior of the bowel was cleaned. A V shaped portion of the mesocolon was excised with the bowel. This gap in the sigmoid mesentery was at once closed by two sutures of No 2 silk. The next step was to partly close the divided end of the greatly distended upper segment until the part left patent should correspond to the lumen of the collapsed bowel below. This was done by means of a continuous suture of the mucous membrane, followed by an outer line of Lembert's suture. For each suture No 1 silk braid was employed, a milliner's needle being used for the continuous suture and a small round Hagedorn's needle for the interrupted stitches. This upper segment of the bowel was as rigid as if made of leather. The two ends of the gut were now joined together in the same way—i.e., by a continuous suture of the mucous membrane and an outer line of Lembert's suture. Whilst I was introducing the interrupted stitches at one end my colleague Mr Openshaw was inserting them at the other. I should judge that about fifty sutures were employed. The assistant's fingers were now relaxed and the contents of the bowel allowed to pass through. It was apparent that the suture line was at all points water tight. The sutured bowel was dropped back into the abdomen and the wound in the parietes was closed in the usual way. The operation occupied one hour and a quarter. The patient was sick three times after the operation, and during the convalescence an injection of morphia was given on three occasions only. The highest temperature reached was 101° on the evening of the second day. The bowels first acted on the third day, when five liquid motions were passed. Between the third and the eighth days the bowels acted twenty-one times. In these motions, which were for the most part liquid, fifteen cherry stones which were swallowed in the previous summer were discovered. The parietal wound was first dressed on the tenth day, when it was found to be soundly healed and all the sutures were removed. On that day the patient was ordered fish. Subsequently to this a slough of mucous membrane containing one of the continuous sutures was discovered in a motion. The patient's recovery was uninterrupted but her discharge from the hospital was delayed by the tardy healing of a bed sore which had formed before the operation. She returned to the country on Jan 18th, 1893. She had been up and walking about for some time before this date, but the bedsores had not quite healed when she returned home. The bowels were now acting regularly without aperients, the abdomen was flat, there were no ascites, no pain and no vomiting. The stricture exhibited the ordinary features of cylindrical epithelioma, and the narrowed passage would barely admit a No 12 catheter.

Wimpole street, W

TWO CASES OF AURAL PYÆMIA TREATED BY OPERATION

By ALFRED PARKIN, M.S., M.D. LOND., F.R.C.S. ENG.,
SENIOR ASSISTANT SURGEON TO THE VICTORIA HOSPITAL, HULL.

It is only recently that cases of septic thrombosis of the lateral sinus following ear disease have been successfully treated. Cases are still recorded from time to time which progress to a fatal termination, and it is only by adoption of a radical method, such as that described and so successfully carried out by Mr W. Arbuthnot Lane,¹ that such a result can be avoided. The following two cases are good examples

of the value of ligaturing the internal jugular vein and removing septic matter from the lateral sinus in patients far advanced in pyæmia, whose recovery without interference was, to say the least, most doubtful.

CASE 1.—A child aged nine years was admitted into the Victoria Hospital, Hull, on Dec. 9th, 1892, suffering from great pain in the head and delirium. He had scarlet fever when three years of age, and had had headaches ever since. On Nov. 27th, 1892, he complained of earache on the right side, and during the succeeding nights was said to have been unconscious. On Dec. 1st otorrhœa came on, and he was sick once. He had diarrhœa on Dec. 7th and 8th, and he had had several bad attacks of shivering. On admission the patient seemed dull and stupid, he complained of severe pain all over the right side of the head. There was a foul discharge from the right ear, with tenderness over the mastoid and over the deep vessels of the neck, the tongue was dry and brown, the eyes were jaundiced and the liver was one inch below the ribs and very tender, there were numerous rales at the base of the right lung, with tubular breathing at one spot, both optic discs were swollen, the right more than the left. The evening temperature was 104.4°. Under chloroform a curved incision was made behind the right ear and a small collection of pus around the aperture of exit of the mastoid vein confirmed the diagnosis. The antrum was first opened by gouging away half an inch of hard bone, it was found to be full of foul pus, which was cleared away, as well as the contents of the middle ear, and the whole cavity disinfected. The bone bounding the lateral sinus was then gouged away and a quantity of extra dural pus extending along the lateral sinus groove was removed. The sinus was obviously thrombosed, consequently the internal jugular vein was exposed low down in the neck. The walls of the vein were so thickened by periphlebitis that it resembled more an empty carotid artery than the normal vein. The vein was tied as low down as possible in two places and the piece excised showed numerous flaky deposits on the intima. The cut ends of the vein were disinfected and the wound sewn up. The lateral sinus was then opened up, as much of the clot as possible scraped out, and the cavity treated with per chloride of mercury solution. A drainage tube was placed in contact with the sinus wall and a second one in the antrum. The next day the headache had gone and the patient's general condition had improved. Convalescence was slow, the lung signs gradually disappeared, the jaundice passed off and the only point of interest in the course of recovery was a rise of temperature to 104° on Dec. 18th, accompanied by severe headache, with marked œdema of the eyelids, especially on the right side. This seemed to indicate a probable extension of the thrombosis to the right cavernous sinus, but the symptoms subsided gradually along with the temperature. The neck wound and greater part of the mastoid wound healed by primary intention, and the patient, after being kept under observation until Feb. 15th, 1893, was discharged in excellent health, all wounds healed (very slight mucoid discharge from the right ear), and able to hear ordinary conversation with the affected ear quite well.

CASE 2.—An infant aged eleven months was admitted into the Victoria Hospital on Dec. 12th, 1892. Three months previously she was in the sanatorium for scarlet fever, and two months afterwards a discharge was first noticed from the left ear, followed in a few days by facial paralysis. She left the sanatorium fourteen days ago, and since then has had several fits, the last a few hours before admission. When admitted the child seemed in a serious condition, she was semi-conscious, her lips were blue, and she called out from time to time, putting her hand up to the left side of her head, the pulse was very rapid, the temperature was subnormal. There was a small swelling behind the left mastoid, about one inch and a half behind the ear, and a foul discharge from the ear itself, the left side of the face was paralysed, bronchial breathing and rales at the base of the left lung were audible, nothing abnormal could be felt in the neck. Under chloroform the small abscess at the back of the mastoid was opened and found to communicate through the foramen of the mastoid vein with the interior of the skull. The antrum was opened and it and the cavity of the middle ear were cleansed of a quantity of foul material. The lateral sinus was exposed and found to be full of broken down clot, which was all scraped away. The internal jugular vein was then exposed, found empty, and tied, there was no periphlebitis at the point of application of the ligature. The recovery in this case was more rapid than in that of the last patient. The facial paralysis and broncho-

¹ Treatment of a case of Pyæmia resulting from Disease of the Middle Ear. THE LANCET Jan. 21st, 1893. Of eight cases so treated seven recovered.

pneumonia gradually disappeared, and the child was discharged on Jan. 14th, 1893, quite well, with no otorrhoea, the wounds healed, and an increase of weight of one pound during the last fortnight of its stay in the hospital.

The diagnosis in the first of these cases was remarkably easy, the patient had symptoms of advanced pyæmia, with a foul otorrhoea, tender swelling over the deep vessels of the neck, and swollen optic discs. How long the septic thrombosis had existed is doubtful, but the case is of interest as indicating how radical treatment may save life even though the pyæmia may have reached an advanced stage. In the second case septic thrombosis of the sinus was only suspected when it was found that the small abscess cavity led through the mastoid vein aperture into the skull. In a patient so young (eleven months) the difficulties of both diagnosis and treatment are much increased, but it was remarkable how soon after the operation the child began to recover, and how rapidly convalescence took place. An early diagnosis followed by prompt removal of the septic foci, is the correct treatment in such cases, and there is no reason to doubt that such treatment may be advantageously applied to other cases of like nature—e.g., umbilical pyæmia. In doubtful cases of middle ear disease, after exploring the mastoid antrum with a gouge, the exposure and examination of the lateral sinus and posterior fossa of the skull, whilst adding greatly to the risk, may succeed in preventing dangerous developments, especially in the case of extra-dural abscesses, which seem to remain latent for some time and then suddenly give rise to meningitis or lateral sinus mischief.

Albion street, Hull.

THE COURSE OF THE INFERIOR LARYNGEAL NERVE

By W. RAMSAY SMITH, M.B., C.M., B.Sc. EDIN

THE late Dr. Herbert Davies's paper on this subject in THE LANCET of Jan. 21st is one of those demonstrations that seem so neat, and the truth of which seems so desirable, that one hesitates to criticise them in case they should break down. As an eminent physician remarked to me recently regarding another physiological problem, "I should feel sorry if it were proved wrong for it is such a pretty piece of physiology." I do not mean to say that Dr. Davies's demonstration is wrong, but I wish to point out one or two things pertinent to the subject that have to be considered before one can say that the explanation given can be said to be complete or proved. It appears to me that Dr. Davies's demonstration involves one or two assumptions that require proof and one or two omissions that must be taken into the calculation. To take them *seriatim* there are—

1. The assumption, running through the whole argument, that respiration is a result of the combined action of the diaphragm and the muscles that open and close the rima glottidis. So far as regards quiet breathing this is not proved. The rima glottidis does not appreciably change its size and shape in normal breathing, and the recurrent laryngeals are not necessary to ordinary breathing. Respiration can go on after section of both recurrent laryngeals the rima glottidis having the patency it usually acquires only after death. It would seem, therefore, that so far as regards ordinary respiration such combined and concerted action between the phrenic and recurrent laryngeal nerves as Dr. Davies supposed does not necessarily occur and it is questionable if it occurs at all. The whole demonstration might be made to turn upon this prime assumption and the proof of it. But in view of the interest that attaches to other parts of the paper I may be pardoned for passing on to them.

2. Suppose it were demonstrated that concerted action between the movements of the vocal cords and the diaphragm were necessary for respiration, the question arises—Is this brought about by the correspondence in length between the phrenic and the recurrent laryngeal nerves? Is it really necessary that the impulses in order to be effective, should pass over the same length of nerve and reach the respiratory nerve terminations at the same instant of time? A first glance seems to be a beautiful and exact demonstration, but two things have to be considered. The first is the difference in length between the right and left

recurrent laryngeal nerves. The impulse by the right must reach the right side of the larynx at a moment appreciably in advance of the impulse that reaches the left side by the left nerve. This difference is considerable, as any one may calculate. The second consideration, which is to the same effect, is that in cases where the right inferior laryngeal nerve does not "recur" but passes straight to the larynx (I refer to the not uncommon condition where the right subclavian artery arises from the arch of the aorta) the proper ratio of lengths of the right and left inferior laryngeals and the phrenics is enormously changed, and yet respiration and voice production go on as usual.

3. Another assumption, a very common one, that seems at first sight self-evident, is that the phrenic nerve by its distribution, in the human body on the inferior surface of the diaphragm is less subject to pressure than if it were distributed on the upper surface. This may or may not be true, but I imagine that any theory at any rate, the ordinary theory, advanced to prove it will be found to involve a nice fallacy in physics.

These three considerations, it appears to me, must be taken into account in estimating the value of Dr. Davies's posthumous contribution. I would add another—viz., the concerted action between the muscles supplied by the superior and the recurrent laryngeal nerves. The subject of the simultaneous innervation of antagonist muscles, especially those concerned in making delicate movements, is almost entirely overlooked in our text-books and in our teaching, but it furnishes the key to a great many difficult problems.

I am not prepared to say that the course of the recurrent laryngeal nerve is not to be explained with reference to the concerted action between the muscles supplied by it and the diaphragm supplied by the phrenic, but it seems to me that Dr. Davies's theory that it is to be so explained involves as many difficulties, if not more, than does the theory that the relative lengths of these nerves have nothing to do with the matter.

Theories of this description are very fascinating. They are often wrong but criticism of them not infrequently points the way to a truer explanation. The works of old masters in science, medicine and philosophy are full of them, some fanciful in the extreme, some evidently erroneous, some seemingly true, yet all requiring rigorous testing. To mention many of those theories would be tedious and useless. I may take, however from my note-books a few instances of theories taught even now that have probably as little foundation in fact as the theories that have been exploded ages ago.

1. Normal knock knee in women is said to be due to the greater width of the pelvis. Let it be granted that the pelvis is wider in women, as it is granted that women possess ovaries—how does width of pelvis explain knock knee? Does width of pelvis explain the greater degree of knock elbow in women?

2. In the act of swallowing the lower jaw, it is said, is firmly applied to the upper. This is said to be necessary in order that the muscles attached to the lower jaw may have a fixed point to act from. But swallowing is possible without fixing the lower jaw to the upper. It is not possible, however without fixing the tongue.

3. Sp. gelus says that the function of the buttocks is to form a cushion on which the body may be softly supported, for the purpose of divine cogitation. Is there any real advance on this theory?

4. It is taught that the great preponderance of muscles inserted on the inner aspect of the tibia is to be explained in relation to the unscrewing of the knee joint at the beginning of the movement of flexion. I have examined this theory in the *Journal of Anatomy and Physiology* and have ventured an explanation that may also cast some light upon the function of the buttocks.

5. The reflex pain in the knee in cases of hip-joint disease is explained by the fact that the obturator nerve supplies both. Is this a real explanation? In this connexion I may state that I have found that stimulation of a spot of skin about an inch to the left of the external occipital protuberance is associated with a corresponding sensation at the same instant referred to a spot just over the tip of the twelfth rib on the left side.

These are only a few instances but they illustrate how very necessary it is to apply a little logical criticism to every theory in anatomy and physiology however well established it may appear to be. Medical science is prone to suffer more from want of well-trained minds than from want of the quantity of investigation.

Inverleith-gardens, Edinburgh.

Clinical Notes :

MEDICAL, SURGICAL, OBSTETRICAL AND THERAPEUTICAL

ON THE ESTIMATION OF SUGAR IN URINE BY THE PICRIC ACID METHOD

By SIR GEORGE JOHNSON, M D LOND, F R S,
CONSULTING PHYSICIAN TO KING'S COLLEGE HOSPITAL AND PHYSICIAN
EXTRAORDINARY TO THE QUEEN

I AM anxious to explain to the profession my reasons for making a slight modification of the standard colour solution which for some years I have used in estimating the amount of sugar in urine. I have recently discovered that the manufacturer of my micro saccharometer has been in the habit of graduating the tube by *external* linear measurement and not by its *internal* capacity. The tubes employed not being of uniform calibre throughout their length, the result has been inaccurate graduation. The standard colour was arrived at by imitating the tint given by a four grain to the ounce solution of pure glucose, boiled with picric acid and potash, according to the method described by me in my two lectures on Albumen and Sugar testing¹ and in the chapter on Sugar testing in my "Medical Lectures and Essays,"² and subsequently diluting four times in the graduated tube. Now, as the upper divisions of the tube were more capacious than the lower, the result was a slight degree of over dilution and a somewhat paler colour than would have been produced in an accurately graduated tube. Inasmuch as the same tube and the same method of procedure were adopted in analysing urines, the results obtained by me have been practically correct. In order to avoid any error in future I have corrected the standard colour solution by imitating the tint produced by diluting a solution of pure glucose in an accurately graduated tube made for me by Mr C E Müller, who will guarantee the accuracy of all graduated tubes supplied by him for my micro saccharometer. The corrected formula for the ferric acetate standard is as follows: One drachm of liquor ferri perchloridi fort. (P B, sp gr 1.42), four drachms of acidum aceticum glaciale (P B, sp gr 1.058), two drachms of liquor ammoniæ (P B, sp gr 0.959), distilled water to four ounces. The only change in this formula consists in the addition of twenty minims of liquor ammoniæ in the four fluid ounces. Since this method of analysis gives extremely accurate results, it has appeared desirable to indicate even so slight a source of error as that which I have here described.

Saville row, W

DEATH OF A CRETIN AGED TWENTY YEARS

By ROBERT KIRK, M D GLASG,
PHYSICIAN TO THE DISPENSARY FOR DISEASES OF WOMEN, GLASGOW
WESTERN INFIRMARY

THIS case was one of five reported in THE LANCET of Aug 23rd and 30th, 1884, where an engraving of it is also shown (case of G B—). The patient was then twelve years of age and was only three feet in height. As he did not grow in the interval and became even more swollen, he presented at last an extraordinary illustration of myxœdema. The trunk was quite globular, the supra clavicular eminenes were enormous and the skin over most of the surface as flabby as that of the eyelids in an ordinary case of the affection. I looked up the case, which I had not seen for several years about a month ago, with the view of giving the patient the benefit of thyroid juice. I found, unfortunately, that he had been ailing for several weeks having lost appetite and become much duller than usual. His pulse was 100 and the temperature 99°, which for him indicated a febrile condition. I suspected some pulmonary affection but the respiratory sounds were so feeble that nothing could be elicited by auscultation and there seemed to be no dulness on percussion. I administered some slightly fried cow's thyroid for two days but as there was no improvement and the parents did not seem anxious to go on with it I desisted. He became gradually worse and in a few days more I found him nearly comatose, breathing stertorously with the

Cheyne-Stokes type of respiration. His mother said his breathing had always been of this character during sleep for the last twelve months. She added that he had often said of late that he would be "choked," although it had never seemed to me at any of my visits that there was much dyspnoea. It was perhaps to be regretted that the treatment was not pushed, as this was just one of the symptoms which ought to have been soon relieved by thyroid feeding. In two cases of myxœdema in adults at present under this treatment (one of which was published in THE LANCET of June 16th, 1888, as a "Case of Tetanic Spasms during Lactation in a Cretinoid Woman") I found the trouble arising from the constant necessity of swallowing mucus wonderfully relieved in two days. Briefly, it may be said that this cretin died of gradual suffocation, brought about by the great submucous œdema of the glottis and air passages. At the recent discussion in Edinburgh Dr Affleck remarked that in one of his cases he had found serious impediment to breathing from œdema of the fauces.

Partick, N B

ON EXCISION OF THE TONSILS

By H A LEDIARD, F R C S ENG &c,
SURGEON TO THE CUMBERLAND INFIRMARY, CARLISLE.

THIS operation is so commonly performed and so constantly needed that it seems not only impossible but unnecessary to add another line to what has already been written on the subject, but it may be that what I wish to say is not familiar to all practitioners. In removing the tonsils I have adhered to the clinical teaching of James Syme, using only a probe pointed curved bistoury and a vulsellum with three prongs to one blade and two to the other, with or without a self retaining tongue depressor. With regard to the guillotine, if that instrument is employed, it will be found that, whilst some tonsils are too large to enter the fenestra of an ordinary instrument, some mouths are too narrow for a large instrument, and therefore three sizes are made by instrument makers, thereby adding considerably to the surgical instrument bill of the surgeon who prefers that method. In using the simple tools that I have named I have made it a practice to remove the left tonsil with the right hand and the right tonsil with the left, holding the vulsellum in the reversed order. A little convenience I have adopted in place of putting a bit of strapping on that part of the bistoury which is not wanted is a piece of rubber tubing slipped over the blade of the knife so as to leave an inch bare at the probed end. This manœuvre is a great help, and it is more than probable that other surgeons have adopted a similar course although I have never seen it mentioned anywhere. It is not often that it is necessary to remove the tonsils of grown up persons, but I have had occasion to remove a tonsil for oft repeated abscesses in the substance with as good results as have followed removal for simple enlargement. As to an anæsthetic, many of my cases have been operated on under chloroform and as many without anything, the surgeon being usually influenced by the age of the patient and the wishes of the parent or guardian. Once I met with primary hæmorrhage lasting some hours and requiring a styptic application. Once only have I met with secondary hæmorrhage, it occurred on the fifth day and caused some alarm as the blood was swallowed and then brought up from the stomach. On March 8th, 1888, I read a few notes on excision of the tonsils before the Carlisle Medical Society, a society then flourishing but now in abeyance, and exhibited a number of tonsils which had been removed for chronic enlargement causing obstruction either to breathing, deglutition or speech, but in no instance have I ever operated when acute disease of the tonsil existed.

Lowther street, Carlisle.

DISLOCATION OF THE HIP OCCURRING IN ACUTE RHEUMATISM

By F E NICHOL, M B, B C CAMB, L.R.C.P LOND &c.

THE following case appears to be an instance of dislocation of the femur on to the dorsum illi occurring without trauma in a child suffering from acute rheumatism.

A female child aged seven years was brought to me o

¹ Smith, Elder and Co, London.

² J & A. Churchill, London.

April 29th, 1890 Her mother stated that for ten weeks the patient had been suffering from chorea. The movements had been most marked in the upper extremities and the tongue, but scarcely noticeable in the lower limbs. About a fortnight before bringing the child she noticed a deformity of the right hip-joint, with bending and shortening of the limb. The child cried when touched or moved, but was free from pain when left at rest. There had been no 'starting' at night. At the beginning of her illness there was swelling heat and pain in the left ankle and knee-joints. No record of temperature observations was obtained. On examination the child was found to be very anæmic and emaciated. She lay with her right thigh adducted and slightly flexed on the abdomen, the knee semi-flexed and the foot inverted, there was marked shortening and the trochanter was one inch above Nelaton's line. In fact, she presented the classical signs of dorsal dislocation of the hip-joint. Gentle attempts to straighten or manipulate the limb gave great pain. With the exception of a loud systolic murmur at the apex of the heart, which was conducted to the axilla and clearly organic, no other physical signs were evident. There were no choreic movements. Chloroform was administered by Dr Arthur Rowe, and no alteration was observed in the deformity. Reduction was easily effected by manipulation and a long outside splint applied. The subsequent history of the case was simple. The child's general health rapidly improved, the splint was removed in three weeks, and the joint was found to be healthy and freely movable. Four months later the father wrote that the child was "quite well save for a slight stiffness."

Cases of dislocation occurring in the course of acute rheumatism are so rarely recorded that it may be well to emphasise the salient features in this case. That it was a true dislocation is evidenced by the shortening flexion and inversion of the limb and by the other marked signs of luxation, by the persistence of these conditions under chloroform, by the immediate restoration of the limb to its proper form by operation and by its rapid and complete recovery. That the child had suffered from acute rheumatism seems clear from the history of pain and swelling of the joints, followed by an attack of chorea, endocarditis and marked anæmia. The mechanism of the occurrence is not quite clear, but it is probable that a certain amount of effusion occurs into the synovial cavity accompanied by inflammatory softening and stretching of the ligaments resulting in displacement of the head of the femur or, as was suggested in an annotation in *THE LANCET*,¹ it may be that owing to the diseased state of the joint the customary co-ordinate support of the muscles is wanting, and that as a result of the inordinate action of a certain group of muscles when the limb is in a 'vicious' attitude the dislocation may be brought about. I have been able to trace few similar cases, the most noteworthy are recorded by Stanley² in England and by Brown³ in America. The annotation in *THE LANCET* referred to above mentions seven cases recorded by M. Verneuil at the Société de Chirurgie, but gives no details.

Elmhurst terrace Margate

SQUAMOUS EPITHELIOMA OF THE EXTERNAL EAR

By W. S. CRAWFORD B.A. CANTAB. F.R.C.S. EDIN.,
ASSISTANT SURGEON LIVERPOOL CANCER AND SKIN HOSPITAL.

THE following case appears to be worth recording on account of the comparative rarity of the affection.

The patient from whom the growth was removed was a man aged sixty-four. He first noticed fourteen months ago a small wart in the upper part of the fossa of the helix. This increased very gradually in size until about seven months since when he received a blow on the side of his head from a cow's tail which caused the warty growth to bleed. After this time it grew more rapidly and spread over to the back part of the ear. It often bled and discharged matter continuously which decomposing gave rise to extreme fetor. When he came under my notice recently the whole of the external ear except the concha and lobule appeared to be composed of an irregular soft warty growth smeared over with fetid pus and a few small blood clots. The mass averaged an inch in thickness, there was very little deep ulceration, and the tumour was particularly soft and papillomatous in character. The growth

was removed by simply slicing the ear off, leaving only the deeper part of the concha, the antitragus and the lobule, no enlarged lymphatic glands could be felt. A microscopical examination of the specimen was made by my friend Mr. Thelwall Thomas. The sections showed well marked squamous epithelioma.

Mount Pleasant Liverpool.

SENSITIVENESS OF THE PERITONEUM

By T. R. JESSOP, F.R.C.S. ENG.,
CONSULTING SURGEON TO THE LEEDS GENERAL INFIRMARY

HAVING occasion a few days ago to perform inguinal colotomy, I asked Mr. Moynihan, our resident surgical officer, to test the sensitiveness of the exposed peritoneum so soon as the patient should have completely recovered from the anæsthetic. Mr. Moynihan informs me that he pricked, scratched and handled the exposed bowel (which appeared to be in no way altered from its normal condition), with the result that the patient declared her sensation was as if she were being 'lightly touched with a feather.' A similar result was obtained from like tests applied to the turned up edge of the parietal peritoneum. At the same time the patient felt acutely the prick of a pin applied to the skin in the neighbourhood of the wound and elsewhere.

Nulla enim est alia pro certo nocendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST THOMAS'S HOSPITAL

TREATMENT OF THE ULCERATIVE LESION IN LARYNGEAL
TUBERCULOSIS, WITH SOME REMARKS ON THE
CONSTITUTIONAL TREATMENT BY LARGE
DOSES OF CREASOTE.

(Under the care of Dr F. SEMON.)

THE following cases of laryngeal, coupled with pulmonary, tuberculosis are quoted to show the effect produced by the internal administration of creasote in large doses and the energetic application of lactic acid locally. No case is reported that had not characteristic lung symptoms so that we can safely assume all the lesions were truly tubercular. It is absolutely essential that the creasote be perfectly pure, as otherwise it may cause dyspepsia, but in estimating the action of the drug we must not forget the frequency of that symptom in phthisis. It must be given immediately after meals and on no account whatever when the stomach is empty. It is taken either in pills or capsules containing one minim of creasote, but so long as the creasote is pure, either are equally efficacious. At first one minim after meals three times a day is given, then after a day or two two minims, and the dose is slowly increased until the patient is taking nine, twelve or even fifteen minims per diem. The solutions of lactic acid used are in the strength of 20 30 40 50 60 and 70 per cent. which are also gradually increased according to the toleration of the larynx and the necessities of the case. In most cases it is not necessary to employ solutions stronger than 40 to 50 per cent. It is applied two three or four times a week, as the case requires, and before every application the larynx is well brushed with a 20 per cent solution of cocaine. After a few minutes the acid is applied on absorbent wool firmly wrapped round rectangular laryngeal forceps. It must be rubbed into the ulcerating part with a very fair amount of force so that the breaking down tissue is removed and the acid comes into direct contact with the floors of the ulcers. Just as in a tuberculous joint the diseased tissue is forcibly scraped so must the larynx be treated, and herein lies the great advantage of firm forceps

¹ THE LANCET, vol. ii. 1893, p. 319.

over a brush or pledget of wool. In cases where there is much oedema, it must first be allowed to subside and inhalations or insufflations of sedatives are to be preferred. It is needless to say that the application must be made under the guidance of the laryngeal mirror, not only because this affords the only certainty that the diseased parts are actually reached, but also because the forcible application of such strong lactic acid solutions to hitherto unaffected parts would be anything but an indifferent measure. In cases in which, in addition to ulceration, there is abundant granulation tissue it may be necessary, previously to the application of the lactic acid, to scrape away the granulations by means of Heryng's or Krause's laryngeal curette. For the following account we are indebted to Mr Marcus A. Dorman, clinical assistant to the throat department.

CASE 1 *Ulcerating swelling in inter arytenoid fold, left cord hidden by granulation tissue, left arytenoid swollen*—A woman aged twenty five

June 20th.—Lungs Left apex, impairment of resonance and some moist sounds. Two minims of creasote were ordered three times a day and the application of a 30 per cent. lactic acid solution twice a week.

July 21st.—All ulceration has disappeared, there is slight granulation tissue on the left ventricular band, but the cord is visible throughout its entire length, the voice is stronger and clearer.

The patient left for India on Aug. 6th, and wrote in October saying that she was still taking capsules, which caused no disagreeable effects. A medical man had examined her throat and stated that it was well. Her cough was much less troublesome and she slept well at night. The patient was then taking nine minims a day.

This case was fortunately treated at a very early stage and was rapidly relieved.

CASE 2 *Swelling and ulceration in inter arytenoid fold &c*—A woman aged twenty seven, occupation housework, weight 9st. 3lb.

Oct. 20th.—Lungs Impairment of resonance of the right apex, but no crepitations. hæmoptysis, night sweats, anæmia, voice weak and hoarse. A 20 per cent. solution of lactic acid was ordered twice a week and two minims of creasote three times a day.

Nov. 17th.—There is less ulceration, ordered nine minims of creasote daily.

Dec. 1st.—Lactic acid discontinued as no ulceration can be seen, weight 9st. 10lb. The hæmoptysis has ceased and the voice is clear and stronger.

This is also an early case and the increase in weight argues well for the treatment.

CASE 3 *Early ulceration of larynx*—A porter aged thirty seven.

July 12th.—The voice is hoarse. Lungs There is dulness at the right apex, with tubular breathing, also much cough and expectoration. A 30 per cent. solution of lactic acid was ordered three times a week and creasote.

Oct. 4th.—The ulcers are healed, and there is some granulation tissue on the cords. The lactic acid has been discontinued but nine minims of the creasote are to be given daily.

Nov. 24th.—The cough is better and there is less expectoration, the patient is gaining in weight. There is no lesion in the larynx.

Dec. 15th.—The voice is normal, the cords are pink, but no ulceration or granulation tissue is to be seen.

The lungs in this case were consolidated at the apices, but the symptoms were much relieved and the larynx healed.

CASE 4 *Much swelling and ulceration on epiglottis, small swelling in inter arytenoid fold, cords quite hidden by granulation tissue*—A man aged fifty two.

July 15th.—Lungs There are signs of extensive cavity in the right upper lobe, cough and expectoration are excessive, the voice is very thick and indistinct. The epiglottis was scraped with a curette and a 40 per cent. solution of lactic acid was applied, and a 30 per cent. solution to the interior of the larynx three times a week. Six minims of the creasote were ordered daily.

28th.—Both cords are visible, the epiglottis is still ulcerating and deglutition is very painful.

Aug. 11th.—There is no ulceration in the larynx, but there is still some on the epiglottis, supervention of melæna. The patient complains that he cannot swallow pills. The lactic acid ordered to be discontinued.

23rd.—There is much swelling of the interior of the larynx. The patient died on Sept. 2nd from general tuberculosis.

This case was so very far advanced that but little could be done. The ulcers in the larynx healed, but the general disease increased. The inability to take the creasote was very unfortunate.

CASE 5 *Ulceration on posterior part of right cord and inter arytenoid fold*—Telegraphist aged twenty seven, weight 8st. 11lb.

Oct. 5th.—Lungs Impairment of resonance, increased vocal resonance and metallic crepitations were audible at the front and back of the right upper lobe. The patient has suffered from hæmoptysis, cough and expectoration for two years. The voice has been thick for seven or eight weeks. A 30 per cent. solution of the lactic acid was ordered twice a week and six minims of creasote daily.

Nov. 11th.—The patient has not attended for three weeks and has not taken the creasote. There are much swelling and ulceration of the larynx and of the arytenoids, so that deglutition is impossible. The throat was painted with cocaine before each meal, which consisted of a pint of milk and two eggs beaten up in it. In three days the swelling had disappeared, and a 50 per cent. solution of the lactic acid was applied, whilst twelve minims of creasote were ordered daily.

24th.—The patient is much better. There is no ulceration and the weight is 8st. 10lb.

The increase of weight here is a proof of the amelioration of the patient's condition. It also illustrates the advantages of such a great excess of fats and proteids—i.e., ten ounces of proteids and fifteen ounces of fat—in enfeebled constitutions.

CASE 6 *Deep excavating ulcer on epiglottis, arytenoids swollen and ulceration in inter arytenoid fold, voice feeble but clear*—A plumber aged forty one. The patient attended at Brompton Hospital in July, 1885, under Dr. Acland. The notes of the case then were "Hæmoptysis sixteen weeks, with cough and expectoration, losing weight."

June 22nd, 1892.—There were signs in both lungs, chiefly in the right. A 20 per cent. solution of the lactic acid was ordered to be applied twice a week and two minims of creasote to be taken three times a day.

July 6th.—The ulcer on the epiglottis was cicatrised. A 40 per cent. solution of lactic acid was ordered and three minims of creasote three times a day.

21st.—There is no ulceration in the larynx. The patient complains of pain shooting down the right side of the neck. He left London for Dover, and discontinued the creasote.

Sept. 4th.—His general condition is worse. There is a white swelling under the anterior part of both cords. There are no ulcers.

Oct. 1st.—He was admitted to hospital, and lactic acid has been continued as required, a 70 per cent. solution frequently being used, his voice is stronger.

Jan. 17th, 1893.—There is no ulceration, but he suffers from pain shooting to the ear, which seems to be temporarily relieved by strong solutions of lactic acid but resists the insufflation of morphia.

This case is undoubtedly slowly progressing, but the immense relief afforded by the lactic acid in deglutition is sufficient warrant for including it here.

CASE 7 *Great swelling of epiglottis which is covered with semi-transparent nodules and granulation tissue, both arytenoids enlarged, so that the cords are only just visible, abundant mucopurulent secretion, voice almost lost*—A shopman aged twenty nine.

Nov. 15th.—Lungs There are signs of cavity at the left apex. A 30 per cent. solution of the lactic acid was ordered three times a week, and two minims of creasote three times a day.

Dec. 7th.—The creasote was increased to three minims three times a day.

Dec. 15th.—The larynx is free from secretion and there are no ulcers to be seen.

Jan. 13th, 1893.—The general health of the patient is improved, he is less anæmic, and the swelling of the larynx has decreased.

This case presented great difficulty in inserting the forceps owing to the extreme swelling of the arytenoids.

CASE 8 *Small ulcerating swelling of inter-arytenoid fold*—A warehouseman aged twenty-seven.

Oct. 18th.—Lungs Crepitations are to be heard at the left apex. One minim of creasote was ordered three times a day and a 20 per cent. solution of the lactic acid twice a week.

Dec. 6th.—No ulceration is to be discerned in the larynx.

Jan. 3rd, 1893.—The patient has been in Brompton Hospital

for six weeks. His cough is better, there is less sputum and no ulceration.

This was an early case, the ulcers soon healed.

Remarks by Dr SEMON.—The above cases illustrate the method of treatment of pulmonary tuberculosis accompanied by laryngeal ulceration which has been practised for the last few years at the Throat Department of St. Thomas's Hospital. This method certainly is a great step in advance upon all the previous modes of treatment recommended during the last ten or fifteen years, and to which a trial has been given in the department. It will of course be understood that the constitutional treatment by large doses of creasote cannot claim in any way, so far as my experience is concerned, to be looked upon as a true specific against tuberculosis, but it can be positively stated from a large experience both in hospital, and even more in private practice, in which the patients more strictly attend to their health, that as a symptomatic treatment it excels every other form at present known. The patients gain in weight, their appetite improves, the night sweats diminish, the expectoration becomes less purulent, and in a good many cases, especially if not coming under observation at too late a period, the disease actually appears to become arrested. Such, at any rate, has been the case in several instances in my private practice, in which I have had the opportunity of watching the patients for periods of two or three years, during which some of them have taken up to 10,000 creasote capsules. Only in very rare instances patients cannot digest the creasote in such large doses, and I would especially warn against looking upon every occasional indigestion as an indication to the effect that the creasote treatment must at once be given up. But it is absolutely necessary, first, that the creasote preparation should be perfectly pure, and, secondly, that the capsules or pills be taken immediately after meals. Concerning the lactic acid treatment of the laryngeal complication, this, too, is a purely symptomatic one, and cannot claim to "cure" the laryngeal disease. Considering, however, how much laryngeal ulcerations, by producing pain, cough and dysphagia, contribute towards hastening the fatal end, any relief to these three serious symptoms is a distinct gain, and it can certainly be said of the lactic acid treatment, as described above, that it surpasses all methods previously recommended in attaining within a comparatively short time, and for a longer period than any other method known to me, the desired effect.

SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH

PAROTITIS FOLLOWING INJURY TO THE ABDOMEN

(Under the care of Mr PAUL SWAIN)

In this case the inflammation of the parotid gland was noticed three weeks after the occurrence of an injury to the abdomen, the nature of which was uncertain. It is a point worthy of note that the severe vomiting ceased when the inflammation of the parotid gland was at its height, and convalescence rapidly followed. The close relationship which exists between the parotid gland and the contents of the abdomen is again exemplified in this case. Our readers will remember the paper on this subject by Mr S. Paget.¹ He found that out of 101 cases 10 followed injury or disease of the urinary tract, 18 of the abdominal wall, subperitoneal or pelvic cellular tissue or peritonium, 50 followed injury, disease or temporary derangement of the generative organs. In 93 out of the 101 cases it was an isolated event, not pyæmic. For the notes of this case we are indebted to Mr Stanley Thomas, house surgeon.

A child aged eleven years on Oct. 21st 1892, fell from a pony injuring her left leg and shaking herself severely. She was admitted to hospital on the 25th, and was found to be suffering from a separation of the lower epiphysis of the left femur. On the 27th she began to vomit. The bowels had not been opened since the day of the accident. The next day she still vomited frequently. The bowels were opened after an enema. On the 31st she seemed better and was able to take milk and lime water. On Nov. 6th she began to vomit again, and on the following day the sickness was very severe and the child looked extremely ill. The tongue was very dry and the abdomen very retracted except in the epigastric region

where there were some fulness, great tenderness and dulness on percussion. The temperature was 99.8° and the pulse very feeble. The child had become emaciated during the past few days. She was fed by nutrient enemata. On the 9th she continued to vomit large quantities of dark green fluid, vomiting as much as from eight to ten ounces at a time. On the 11th slight swelling and great tenderness were noticed in the region of the left parotid gland, to which fomentations were applied. The next day the parotid was very swollen and looked as if it would suppurate. On the 14th the sickness had stopped. The patient was then taking peptonised milk.

Nov. 24th.—The child has not suffered from sickness since the 14th, there is no tenderness across the abdomen, the dulness has gone and the inflammation of the parotid has quite subsided. The patient left the hospital on Dec. 9th quite well.

Medical Societies.

MEDICAL SOCIETY OF LONDON

Annual General Meeting—Supra-pubic Prostatectomy

THE annual general meeting of this Society was held on March 6th, the President, Mr Hutchinson, in the chair.

The annual report of the Council was submitted, together with statements from the treasurer and honorary librarian. The financial position was stated to be very satisfactory, and the number of Fellows had considerably increased during the past year. The Fothergillian Medal and Honorary Premium were awarded to Dr W. R. Gowers for his Contributions to Practical Medicine, and in especial recognition of his work on Diseases of the Nervous System. The following officers were elected for the ensuing year—President, Dr John Syer Bristowe. Vice Presidents, Dr F. de Havilland Hall, Dr F. T. Roberts, Mr D. H. Goodsall and Mr F. Treves. Treasurer, Mr A. E. Durham. Librarian, Dr W. H. Allchin. Honorary Secretaries, Dr W. Pasteur and Mr C. B. Lockwood. Honorary Secretary for Foreign Correspondence, Dr Heinrich Port. Council, Dr W. Collier (Oxford), Dr C. J. Callagrowth, Dr T. Colcott Fox, Dr A. E. Garrod, Dr Gerald S. Harper, Dr G. A. Heron, Dr Stephen Mackenzie, Dr E. D. Mapother, Dr H. Montague Murray, Dr Samuel West, Mr H. F. Bailey, Mr C. A. Ballance, Mr G. Buckston Browne, Mr J. Cahill, Mr F. Swinford Edwards, Mr J. Hutchinson, Mr A. Cooper Key, Mr A. Marmaduke Shield, Mr G. R. Turner, and Mr W. Whitehead (Manchester).

Mr BUCKSTON BROWNE read a paper on Supra-pubic Prostatectomy. He began by pointing out that surgically the prostate must be considered as one single organ, its division into lobes was purely arbitrary. It was a sexual organ and only became concerned in the function of micturition when it became hypertrophied or enlarged. Chronic prostatic hypertrophy was (1) intra-vesical, (2) extra-vesical, or (3) both intra and extra-vesical. The intra-vesical enlargement was the chief cause of difficulty in micturition. This intra-vesical growth was often like an egg projecting into the bladder, with the vesical urethral orifice at the apex of the egg. This ovoid projection might be deficient at any part of the urethral circumference. When wanting anteriorly and laterally, there was the so-called middle lobe enlargement, where from behind the urethral orifice there was a projecting prostatic mass acting like a bullet valve and often causing the bladder to be entirely dependent upon the use of a catheter for the voidance of its urine. More rarely the ovoid projection was only wanting in front, or it might be only on one side, in such cases it was nearly always continuously combined with a posterior enlargement, whilst so rarely as practically to be never met with, the intra-vesical growth was only found anteriorly to the urethral orifice. Intra-vesical prostatic outgrowths might be associated with considerable extra-vesical enlargement, and the latter might exist without the former and cause the patient so afflicted to be partially or completely dependent upon his catheter. He expressed the opinion that the intra-vesical growth alone could be removed with reasonable safety and with a fair prospect of recovery of the power of natural micturition. Without digital examination after supra-pubic cystotomy, it could only be approximately diagnosed. All urethrometers and the electric endoscope were useless and dangerous, the danger from their use being the likelihood of their causing severe urethral or catheter fever. There were, however, two

over a brush or pledget of wool. In cases where there is much œdema, it must first be allowed to subside and inhalations or insufflations of sedatives are to be preferred. It is needless to say that the application must be made under the guidance of the laryngeal mirror, not only because this affords the only certainty that the diseased parts are actually reached, but also because the forcible application of such strong lactic acid solutions to hitherto unaffected parts would be anything but an indifferent measure. In cases in which, in addition to ulceration, there is abundant granulation tissue it may be necessary, previously to the application of the lactic acid, to scrape away the granulations by means of Heryng's or Krause's laryngeal curette. For the following account we are indebted to Mr Marcus A. Dorman, clinical assistant to the throat department.

CASE 1 *Ulcerating swelling in inter arytenoid fold, left cord hidden by granulation tissue, left arytenoid swollen*—A woman aged twenty five.

June 20th.—Lungs. Left apex, impairment of resonance and some moist sounds. Two minims of creosote were ordered three times a day and the application of a 30 per cent. lactic acid solution twice a week.

July 21st.—All ulceration has disappeared, there is slight granulation tissue on the left ventricular band, but the cord is visible throughout its entire length, the voice is stronger and clearer.

The patient left for India on Aug. 6th, and wrote in October saying that she was still taking capsules, which caused no disagreeable effects. A medical man had examined her throat and stated that it was well. Her cough was much less troublesome and she slept well at night. The patient was then taking nine minims a day.

This case was fortunately treated at a very early stage and was rapidly relieved.

CASE 2 *Swelling and ulceration in inter arytenoid fold &c*—A woman aged twenty seven, occupation housework, weight 9st. 3lb.

Oct. 20th.—Lungs. Impairment of resonance of the right apex, but no crepitations. Hemoptysis, night sweats, anæmia, voice weak and hoarse. A 20 per cent. solution of lactic acid was ordered twice a week and two minims of creosote three times a day.

Nov. 17th.—There is less ulceration, ordered nine minims of creosote daily.

Dec. 1st.—Lactic acid discontinued as no ulceration can be seen, weight 9st. 10lb. The hæmoptysis has ceased and the voice is clear and stronger.

This is also an early case and the increase in weight argues well for the treatment.

CASE 3 *Early ulceration of larynx*—A porter aged thirty seven.

July 12th.—The voice is hoarse. Lungs. There is dulness at the right apex, with tubular breathing, also much cough and expectoration. A 30 per cent. solution of lactic acid was ordered three times a week and creosote.

Oct. 4th.—The ulcers are healed, and there is some granulation tissue on the cords. The lactic acid has been discontinued but nine minims of the creosote are to be given daily.

Nov. 24th.—The cough is better, and there is less expectoration, the patient is gaining in weight. There is no lesion in the larynx.

Dec. 15th.—The voice is normal, the cords are pink, but no ulceration or granulation tissue is to be seen.

The lungs in this case were consolidated at the apices, but the symptoms were much relieved and the larynx healed.

CASE 4 *Much swelling and ulceration on epiglottis, small swelling in inter arytenoid fold, cords quite hidden by granulation tissue*—A man aged fifty two.

July 15th.—Lungs. There are signs of extensive cavity in the right upper lobe, cough and expectoration are excessive, the voice is very thick and indistinct. The epiglottis was scraped with a curette and a 40 per cent. solution of lactic acid was applied, and a 30 per cent. solution to the interior of the larynx three times a week. Six minims of the creosote were ordered daily.

28th.—Both cords are visible, the epiglottis is still ulcerating and deglutition is very painful.

Aug. 11th.—There is no ulceration in the larynx, but there is still some on the epiglottis, supraventricular of mæna. The patient complains that he cannot swallow pills. The lactic acid ordered to be discontinued.

23rd.—There is much swelling of the interior of the larynx. The patient died on Sept. 2nd from general tuberculosis.

This case was so very far advanced that but little could be done. The ulcers in the larynx healed, but the general disease increased. The inability to take the creosote was very unfortunate.

CASE 5 *Ulceration on posterior part of right cord and inter arytenoid fold*—Telegraphist aged twenty seven, weight 8st. 11lb.

Oct. 5th.—Lungs. Impairment of resonance, increased vocal resonance and metallic crepitations were audible at the front and back of the right upper lobe. The patient has suffered from hæmoptysis, cough and expectoration for two years. The voice has been thick for seven or eight weeks. A 30 per cent. solution of the lactic acid was ordered twice a week and six minims of creosote daily.

Nov. 11th.—The patient has not attended for three weeks and has not taken the creosote. There are much swelling and ulceration of the larynx and of the arytenoids, so that deglutition is impossible. The throat was painted with cocaine before each meal, which consisted of a pint of milk and two eggs beaten up in it. In three days the swelling had disappeared, and a 50 per cent. solution of the lactic acid was applied, whilst twelve minims of creosote were ordered daily.

24th.—The patient is much better. There is no ulceration and the weight is 8st. 10lb.

The increase of weight here is a proof of the amelioration of the patient's condition. It also illustrates the advantages of such a great excess of fats and proteids—i.e., ten ounces of proteids and fifteen ounces of fat—in enfeebled constitutions.

CASE 6 *Deep excavating ulcer on epiglottis, arytenoids swollen and ulceration in inter arytenoid fold, voice feeble but clear*—A plumber aged forty one. The patient attended at Brompton Hospital in July, 1885, under Dr. Acland. The notes of the case then were "Hæmoptysis sixteen weeks, with cough and expectoration, losing weight."

June 22nd, 1892.—There were signs in both lungs, chiefly in the right. A 20 per cent. solution of the lactic acid was ordered to be applied twice a week and two minims of creosote to be taken three times a day.

July 6th.—The ulcer on the epiglottis was cicatrised. A 40 per cent. solution of lactic acid was ordered and three minims of creosote three times a day.

21st.—There is no ulceration in the larynx. The patient complains of pain shooting down the right side of the neck. He left London for Dover, and discontinued the creosote.

Sept. 4th.—His general condition is worse. There is a white swelling under the anterior part of both cords. There are no ulcers.

Oct. 1st.—He was admitted to hospital, and lactic acid has been continued as required, a 70 per cent. solution frequently being used, his voice is stronger.

Jan. 17th, 1893.—There is no ulceration, but he suffers from pain shooting to the ear, which seems to be temporarily relieved by strong solutions of lactic acid but resists the insufflation of morphia.

This case is undoubtedly slowly progressing, but the immense relief afforded by the lactic acid in deglutition is sufficient warrant for including it here.

CASE 7 *Great swelling of epiglottis which is covered with semi-transparent nodules and granulation tissue, both arytenoids enlarged, so that the cords are only just visible, abundant mucopurulent secretion, voice almost lost*—A shopman aged twenty nine.

Nov. 15th.—Lungs. There are signs of cavity at the left apex. A 30 per cent. solution of the lactic acid was ordered three times a week, and two minims of creosote three times a day.

Dec. 7th.—The creosote was increased to three minims three times a day.

Dec. 15th.—The larynx is free from secretion and there are no ulcers to be seen.

Jan. 13th, 1893.—The general health of the patient is improved, he is less anæmic, and the swelling of the larynx has decreased.

This case presented great difficulty in inserting the forceps owing to the extreme swelling of the arytenoids.

CASE 8 *Small ulcerating swelling of inter-arytenoid fold*—A warehouseman aged twenty seven.

Oct. 18th.—Lungs. Crepitations are to be heard at the left apex. One minim of creosote was ordered three times a day and a 20 per cent. solution of the lactic acid twice a week.

Dec. 6th.—No ulceration is to be discerned in the larynx.

Jan. 3rd, 1893.—The patient has been in Brompton Hospital

Mr BUCKSTON BROWNE, in reply, said that many cases were on record where portions of the prostate had been removed by the forceps while extracting a stone, but these, as a rule, had not been followed by restoration of the powers of micturition, because the prostatic removal had not been complete. He had seen cases where there had been trouble from perineal fistula. Of the rubber catheter he would say that if it passed at all a child could do it, but that if it would not go easily the best surgeon would not be able to make it do so. Two pockets were often formed, one on each side of the veru montanum, and these often acted as a bar to soft instruments and might in a few cases necessitate the use of a silver one. With regard to the presence of kidney disease, it should be remembered that the cases were often desperate ones, not permitting of selection. In the perineal operation the cut must to a certain extent be in the dark, and he had seen severe hæmorrhage follow this method.

PATHOLOGICAL SOCIETY OF LONDON

Survey of Recent Work bearing on the Pathology of Cancer and Sarcoma

AN ordinary meeting of this Society was held on March 7th, the President, Sir George Humphry, in the chair.

The debate on the Pathology of Cancer and Sarcoma was resumed by Mr RUBERT BOYCE, who detailed the results of researches on cell inclusions in cancer which had been made by himself and Dr Arthur Giles. He showed micro-photographs illustrating some phases of cancer bodies which they had recently met with in a case of carcinoma of the pancreas. The sections were all equally and highly magnified, they were hardened in alcohol and stained with logwood. As Dr Galloway hinted at the last meeting, in his clear summary of his own broad views they were inclined, from want of stronger evidence, to believe that many of the parasitic bodies so recently described in cancer cells were not parasitic, but of the nature of endogenous cells. Whilst the processes of cell invagination and of nuclear and cell plasma degeneration had been discussed by those holding the parasitic view, endogenous cell formation had been briefly dismissed or left out of account, yet this process was the one *par excellence* which must be sharply differentiated from parasitic enclosures for the endogenous cell and the parasite were alike nucleated protoplasmic masses and the unicellular parasites of certain mollusca as well as those found occasionally in the alimentary tract and lungs of man, showed how very difficult it was to distinguish between the parasites and certain cells of the host. The confounding of the two in the past had led to curious mistakes upon both sides—notably on the one hand, in the mistaking of the parasites of the blood-corpuscles of the frog for active phenomena of the protoplasm of the corpuscles themselves, and, on the other hand, in regarding certain nuclear forms as parasites. Arnold who had done for pathological mitosis what Flemming did for the normal process, described and figured endogenous cell formation in the giant cells of marrow, of tuberculous glands and of neoplasms. A glance at his figures showed how closely this phenomenon resembled the appearances of parasitism as described by recent observers. Recently a paper had appeared from Arnold's laboratory by Müller in which the parasites described by Drs. Ruffer and Walker were regarded as typical examples of endogenous cell formation. Müller's figures agreed with the photographs they were showing and they thought that they were correct in saying that both were identical with the appearances described and figured by Drs. Ruffer and Walker, Dr Galloway, Mr Clarke and others. Their preparations showed—1. That the cell enclosures were met with in abnormal cells. They were giant forms, there was very often more than one nucleus, there was the very marked hyperchromatosis so characteristic of many forms (especially giant forms) of sarcoma and carcinoma cells. There were evident signs in many of the giant cells of drooping of the plasma. This droopical condition was represented by a loose reticulation of the cell substance or by the formation of groups of vacuoles. These observations accorded with those of Müller. 2. That the cell enclosures were single or multiple and that they usually commenced in or near the nucleus or that they occupied the place of the nucleus. These observations agreed with those of Arnold, in which the nucleus of the included cell was often connected by fine chromatin strands with the mother nucleus. 3. That the enclosures consisted either of little else than chromatin granules or of a nucleus and protoplasm. That the chromatin

of the enclosed cells might be broken up into several pieces or may appear as if about to divide. The chromatin might be separated by an enclosing vacuole from the rest of the cell, and often stained just like the nucleolus of the mother nucleus. 4. That there was a capsule which was regarded by Dr Ruffer as formed by the cancer cell itself. Dr Galloway observed that it might be radially striated and they had met with one very marked example of this. They called attention to a highly important and little known observation of Flemming—namely that the capsule of the fat cell was highly differentiated and might give a distinct staining reaction. With regard to the explanation of the thickened and striated capsules, perhaps some information might be obtained from Stilling's observation upon the encapsuled endogenous bodies found in the prostate. 5. That the capsule expanded, either by the growth of the enclosed body or by the accumulation of fluid. Capsules might, in fact, contain perfect cell enclosures, large or small granular masses (spore-like bodies) fine granular debris, or only fluid. They had found all connecting stages of these conditions. 6. That when several capsules were formed in the same cell or in close proximity a mulberry mass resulted comparable to the mulberry fat cells (derived from one cell) of certain of the lower animals. The partitions might however, rupture and fusion occur. 7. That capsules were met with enclosing more than one nucleated body. There might be two or more perfectly formed cells, or, on the other hand, very degenerate masses. These groups appeared to them a most suggestive feature from the point of view of parasitism. 8. That there was not the least trace of irritation or leucocytic reaction in the neighbourhood of the cell enclosures, and that the cancer cells in these parts did not show any greater signs of activity than elsewhere. From the above facts they did not feel justified in concluding that these bodies were parasites, and the great variety of appearances described by different observers seemed to them rather to favour the non parasitic view. Mr Boyce and Dr Giles were of opinion that Mr Clarke brought forward to the Society no evidence whatever to show that both cancer and sarcoma were caused by the parasites in the same sense that tubercle was caused by the tubercle bacilli. Cancer gave rise to metastasis, but the secondary foci, unlike tubercle and the infective processes generally, were grafts of the original focus, which did not, in so far as we at present knew, confer their malignancy or their infectivity on the tissues around. Mr Clarke and Dr Galloway admitted as parasites free nucleated bodies, described as amoeboid by Mr Clarke, in the intercellular spaces. Dr Ruffer and others, on the other hand, restricted the term 'parasite' to encapsuled cell enclosures. From the analogy of parasites in the lower animals the one view had at least as much in its favour as the other. Cancer bodies had been freely compared with and called "sporozoa", they would, however call attention to the following points in which cancer bodies and sporozoa were in marked contrast. 1. The intracellular sporozoa (sarcosporidia) seemed to be of a harmless nature, not causing inconvenience to their host (Bütschli), but rather living on terms of symbiosis, which is well illustrated in the paramœcium, where it might be even hereditary, but, to quote Dr Ruffer, 'the life of the parasites in the cancer cells is a precarious one, whilst they cause their hosts to perish.' 2. Sarcosporidia were nearly always large and visible to the naked eye. 3. The cystic, or resting stage of sporozoa was the only one represented at all definitely among cancer bodies. They never saw the active amoeboid stage, pseudopodia or ciliated forms as seen in Coccidia and Klossia. 4. The numerous round lenticular or falciform spores so characteristic of sporozoa, were never seen in cancer. 5. The bodies which had been compared to spores were clear, like fat globules and of unequal size. Spores of sarcosporidia were invariably of uniform size and generally granular. 6. The spores of gregarinids always had a silicious or chitinous capsule. To conclude they must still agree with what Virchow said eighteen years ago and which he had recently repeated—namely that as no previous and no subsequent stages of these bodies could be traced, therefore there was not sufficient evidence as yet in support of their parasitic nature.

Mr D ARCY POWER showed some photographs of cells of squamous epithelium taken from a rat in which a wound had been made and artificial irritation had been kept up for some time. The cells were much larger than the ordinary run of epithelial cells and they showed appearances which simulated those found in carcinoma.

Dr WOODHEAD said that he felt somewhat disappointed that it had not been possible to adhere to the original pro-

simple means of examination—namely, digital rectal examination and the careful measuring of the length of the urethra by means of the simple passage of the catheter. Any undue length of urethra would be an argument in favour of intra vesical hypertrophy, and particularly so if, per rectum, the prostate was felt but little enlarged. If much extra vesical growth was found, this must be allowed for in estimating the importance of the length of the urethra. If the urethra was nine inches long or more, and if not much growth could be felt by the rectum, there was almost sure to be intra vesical hypertrophy. Should it be deemed desirable to sound the patient for stone, further evidence for or against the presence of intra vesical growth would be obtained, for if such growth existed it would be found that the sound had to travel very much uphill into the bladder. It was then pointed out that a man with slight prostatic hypertrophy might live comfortably until exposed to any circumstances causing congestion of the prostate, and that then the catheter might be required, and used even for months, and the power of natural micturition return after all. Such cases must not be submitted to prostatectomy. Unhappily prostatic retention, whether partial or complete, generally came prepared to stay. The prospects of a man obliged to pass his urine by catheter were very good, and there was not the slightest need for him to undergo a severe operation such as prostatectomy at the outset of his catheter life. If he attended to the toilet of his bladder (which was briefly detailed) all would be well, unless the intra vesical growth was very large, such a growth would baffle every precaution and should be removed. In some rare cases regular habitual auto catheterism was so difficult that life under such conditions was not worth having. This difficulty might arise from the great curve of the prostatic urethra, the existence of false passages, and sometimes from the great ease with which the prostate would bleed if impinged upon and injured by the catheter, filling the catheter with blood clot, thus preventing the emptying of the bladder, and causing vesical spasm, as well as exhausting the patient by the constant loss of blood. Occasionally also patients were met with whose hands were crippled by rheumatism or by nervous affections, or who only possessed one hand, or whose special occupations made auto catheterism difficult or even almost impossible. In all these cases supra pubic prostatectomy since 1886 had become a practicable operation. The possibility of recovery of the bladder after complete removal of prostatic obstruction had been doubted by great authorities, but he gave full details of a case which was an answer in the affirmative, the gentleman operated upon being present at the meeting and the facts being beyond dispute. With reference to the details of the operation of supra pubic prostatectomy, the operation should always be extra peritoneal, all intra peritoneal operations must add largely to the risk, and all that was necessary could be done through an extra peritoneal incision. The bladder should always be opened upon a staff, if not, since the body of the prostate in these cases was frequently very large, it was very likely to be incised instead of the bladder. In removing the projecting prostate with forceps it should be twisted off in one piece if small, piecemeal if large. By twisting or torsion hæmorrhage was lessened. The intra vesical growth should alone be attacked, no good would come of trying to remove the lateral lobes, even in part. In clearing the vesical urethral orifice of all surrounding projecting prostatic tissue much assistance would be obtained by the presence of a metal sound in the urethra. Hæmorrhage was usually very free and would be all the more so if the prostate had been attacked with knife or scissors, the use of both of which instruments was deprecated. Dr Keyes had suggested a lint tampon drawn into the prostatic urethra by a thread through the urethra, but Mr Browne had found the bleeding sufficiently controlled by hot water irrigation, and all plugs must add to the patient's pain. In conclusion, he expressed his present opinions as follows: 1. Supra pubic prostatectomy should never be undertaken at the outset of catheter life unless regular auto catheterism was impossible. 2. The operation should never be undertaken as long as the ordinary catheter life was a tolerable one. 3. If, from any of the causes detailed catheter life became intolerable, supra pubic cystotomy should be resorted to. By means of this proceeding the bladder could be thoroughly explored and any stone removed, which in these cases might easily have escaped detection by the more usual methods of examination. The intra vesical growth, if it were found to exist, could be fully examined and removed if the operator thought right to do so. If he deemed removal undesirable, or if there was nothing which could be removed, he could

leave the patient with a supra pubic tube for permanent after wear, with the certainty that he would have materially improved the condition of the patient. 4. Should the operator decide to remove the prostatic obstruction, there was a very good prospect, but not a certainty, of the power of natural micturition being restored to the patient.

The PRESIDENT alluded to the impartial character of the paper and regarded the conclusions as both wise and safe. He agreed that it was not advisable to interfere with anything more than the intra vesical portion of the growth, though Mr McGill had undertaken the removal of a great deal more. Some excisions of the middle lobe had been performed accidentally during lithotomy, when portions of prostatic growth lay in front of the stone and had been pulled out by the forceps as the calculus was being extracted. He himself had once done this and as he found that other portions of growth were removable he cleared the whole floor of the bladder. This was done five years ago and the patient had made a perfect recovery. He agreed that enlargement of the prostate was a cause and not a consequence of bladder disease. He held that the old fashioned silver catheter was a bad instrument for routine use and that a rubber catheter was much the best, the patient easily introducing it himself and an upward curve of the urethra not interfering with its introduction.

Mr REGINALD HARRISON asked Mr Browne whether he had limited his operative procedures to the method which he had described. He himself recognised prostatic obstruction as of two kinds. 1. A growth into the bladder of considerable masses of prostatic tissue, causing not only obstruction but cystitis. These should be treated, like bladder tumours, by removal by supra pubic cystotomy. 2. In a certain proportion the obstruction was due to formation of "collars" or girths of prostatic tissue round the neck of the bladder occluding the urethral orifice like a vice. He would not apply the supra pubic operation to the latter class, such a procedure being protracted, severe and sanguinary. At the Congress at Copenhagen he had described a method he had adopted of dividing these collars in a few instances by a perineal incision and the introduction of a drainage-tube. Since that paper, which was read about ten years ago he had operated eighteen times, in ten instances with partial or complete restoration of micturition after long periods of constant catheterism, one of these cases he proceeded to give in detail. In the entire series he could not recall a single instance of perineal fistula or of severe hæmorrhage.

Mr BRUCE CLARK, referring to the question of diagnosis, said that the enlargement might be either in the course of the urethra, at the neck of the bladder, or in the bladder itself. If within the organ, the growth should always be removed. With a bimanual examination under chloroform one might get a very fair idea of the size of the prostate. The most difficult cases of all to deal with were those in which the urethra was compressed by an upgrowth from its floor. After making a supra pubic opening, the portion of prostate extending into the bladder might be, in some cases, successfully treated without removal by touching it with the galvanocautery or with Paquelin's instrument. He held that twisting out portions of prostate courted hæmorrhage, but that if the growth were got away by degrees, and the base touched with the cautery, not much blood need be lost.

Mr SWINFORD EDWARDS, after discussing the connexion between sexual exercise and prostatic hypertrophy remarked that the electric light was not a success as an aid to diagnosis. For this purpose he preferred a short-beaked sound with a finger in the rectum, which would often enable one to determine the kind of enlargement present. He had known the hypertrophy to be present before the age of fifty. If a pedunculated ingrowth were diagnosed, the sooner it were removed the better, and he thought that it was unwise to wait for the changes associated with catheter life. No attempt should be made to remove a "collar" by supra pubic prostatectomy.

Mr SHEILD asked whether silver catheters should be used at all in prostatic cases. He regarded them as dangerous instruments, especially if used on the first occasion when a catheter was required. The prostate varied much as to its vascular condition and was apt to be much engorged when a stone was present. Very severe hæmorrhage followed in the only two cases of prostatectomy he had witnessed. Everything depended on a proper selection of cases. Bad subjects were old and fat men, especially those with bronchitis and emphysema and those with kidney trouble, whether that were indicated by the presence of albuminuria or by the passage of an excessive quantity of urine with a low percentage of urea.

Mr BUCKSTON BROWNE, in reply, said that many cases were on record where portions of the prostate had been removed by the forceps while extracting a stone, but these, as a rule, had not been followed by restoration of the powers of micturition, because the prostatic removal had not been complete. He had seen cases where there had been trouble from perineal fistula. Of the rubber catheter he would say that if it passed at all a child could do it, but that if it would not go easily the best surgeon would not be able to make it do so. Two pockets were often formed, one on each side of the veru montanum, and these often acted as a bar to soft instruments and might in a few cases necessitate the use of a silver one. With regard to the presence of kidney disease, it should be remembered that the cases were often desperate ones, not permitting of selection. In the perineal operation the cut must to a certain extent be in the dark, and he had seen severe hæmorrhage follow this method.

PATHOLOGICAL SOCIETY OF LONDON

Survey of Recent Work bearing on the Pathology of Cancer and Sarcoma

An ordinary meeting of this Society was held on March 7th, the President, Sir George Humphry, in the chair.

The debate on the Pathology of Cancer and Sarcoma was resumed by Mr ROBERT BOYCE, who detailed the results of researches on cell inclusions in cancer which had been made by himself and Dr Arthur Giles. He showed micro photographs illustrating some phases of cancer bodies which they had recently met with in a case of carcinoma of the pancreas. The sections were all equally and highly magnified, they were hardened in alcohol and stained with logwood. As Dr Galloway hinted at the last meeting, in his clear summary of his own broad views, they were inclined, from want of stronger evidence, to believe that many of the parasitic bodies so recently described in cancer cells were not parasitic, but of the nature of endogenous cells. Whilst the processes of cell invagination and of nuclear and cell plasma degeneration had been discussed by those holding the parasitic view, endogenous cell formation had been briefly dismissed or left out of account, yet this process was the one *par excellence* which must be sharply differentiated from parasitic enclosures, for the endogenous cell and the parasite were alike nucleated protoplasmic masses, and the unicellular parasites of certain mollusca, as well as those found occasionally in the alimentary tract and lungs of man, showed how very difficult it was to distinguish between the parasites and certain cells of the host. The confounding of the two in the past had led to curious mistakes upon both sides—notably on the one hand, in the mistaking of the parasites of the blood corpuscles of the frog for active phenomena of the protoplasm of the corpuscles themselves, and, on the other hand, in regarding certain nuclear forms as parasites. Arnold, who had done for pathological mitosis what Flemming did for the normal process, described and figured endogenous cell formation in the giant cells of marrow, of tuberculous glands and of neoplasms. A glance at his figures showed how closely this phenomenon resembled the appearances of parasitism as described by recent observers. Recently a paper had appeared from Arnold's laboratory by Müller in which the parasites described by Drs. Ruffer and Walker are regarded as typical examples of endogenous cell formation. Müller's figures agreed with the photographs they were showing and they thought that they were correct in saying that both were identical with the appearances described and figured by Drs. Ruffer and Walker, Dr Galloway, Mr Clarke and others. Their preparations showed—1. That the cell enclosures were met with in abnormal cells. They were giant forms, there was very often more than one nucleus, there was the very marked hyperchromatism so characteristic of many forms (especially giant forms) of sarcoma and carcinoma cells. There were evident signs in many of the giant cells of dropsy of the plasma. This dropsical condition was represented by a loose reticulation of the cell substance or by the formation of groups of vacuoles. These observations accorded with those of Müller. 2. That the cell enclosures were single or multiple, and that they usually commenced in or near the nucleus or that they occupied the place of the nucleus. These observations agreed with those of Arnold, in which the nucleus of the included cell was often connected by fine chromatin strands with the mother nucleus. 3. That the enclosures consisted either of little else than chromatin granules or of a nucleus and protoplasm. That the chromatin

of the enclosed cells might be broken up into several pieces or may appear as if about to divide. The chromatin might be separated by an enclosing vacuole from the rest of the cell, and often stained just like the nucleolus of the mother nucleus. 4. That there was a capsule which was regarded by Dr Ruffer as formed by the cancer cell itself. Dr Galloway observed that it might be radially striated and they had met with one very marked example of this. They called attention to a highly important and little known observation of Flemming's—namely, that the capsule of the fat cell was highly differentiated and might give a distinct staining reaction. With regard to the explanation of the thickened and striated capsules, perhaps some information might be obtained from Stilling's observation upon the encapsuled endogenous bodies found in the prostate. 5. That the capsule expanded, either by the growth of the enclosed body or by the accumulation of fluid. Capsules might, in fact, contain perfect cell enclosures, large or small granular masses (spore like bodies), fine granular debris, or only fluid. They had found all connecting stages of these conditions. 6. That when several capsules were formed in the same cell or in close proximity a mulberry mass resulted comparable to the mulberry fat cells (derived from one cell) of certain of the lower animals. The partitions might however, rupture and fusion occur. 7. That capsules were met with enclosing more than one nucleated body. There might be two or more perfectly formed cells, or, on the other hand, very degenerate masses. These groups appeared to them a most suggestive feature from the point of view of parasitism. 8. That there was not the least trace of irritation or leucocytic reaction in the neighbourhood of the cell enclosures, and that the cancer cells in these parts did not show any greater signs of activity than elsewhere. From the above facts they did not feel justified in concluding that these bodies were parasites, and the great variety of appearances described by different observers seemed to them rather to favour the non parasitic view. Mr Boyce and Dr Giles were of opinion that Mr Clarke brought forward to the Society no evidence whatever to show that "both cancer and sarcoma were caused by the parasites in the same sense that tubercle was caused by the tubercle bacilli." Cancer gave rise to metastasis, but the secondary foci, unlike tubercle and the infective processes generally, were grafts of the original focus, which did not, in so far as we at present knew, confer their malignancy or their infectivity on the tissues around. Mr Clarke and Dr Galloway admitted as parasites free nucleated bodies, described as amœboid by Mr Clarke, in the intercellular spaces. Dr Ruffer and others, on the other hand, restricted the term "parasite" to encapsuled cell enclosures. From the analogy of parasites in the lower animals the one view had at least as much in its favour as the other. Cancer bodies had been freely compared with and called "sporozoa", they would, however, call attention to the following points, in which cancer bodies and sporozoa were in marked contrast. 1. The intracellular sporozoa (sarcosporidia) seemed to be of a harmless nature, not causing inconvenience to their host (Bütschli), but rather living on terms of symbiosis, which is well illustrated in the paramœcium where it might be even hereditary, but, to quote Dr Ruffer, "the life of the parasites in the cancer cells is a precarious one," whilst "they cause their hosts to perish." 2. Sarcosporidia were nearly always large and visible to the naked eye. 3. The cystic, or resting, stage of sporozoa was the only one represented at all definitely among cancer bodies. They never saw the active amœboid stage, pseudopodia or ciliated forms as seen in Coccidia and Klossia. 4. The numerous round lenticular or falciform spores, so characteristic of sporozoa were never seen in cancer. 5. The bodies which had been compared to spores were clear, like fat globules and of unequal size. Spores of sarcosporidia were invariably of uniform size and generally granular. 6. The spores of gregarinidæ always had a silicious or chitinous capsule. To conclude they must still agree with what Virchow said eighteen years ago and which he had recently repeated—namely, that as no previous and no subsequent stages of these bodies could be traced, therefore there was not sufficient evidence as yet in support of their parasitic nature.

Mr D'ARCY POWER showed some photographs of cells of squamous epithelium taken from a rat in which a wound had been made and artificial irritation had been kept up for some time. The cells were much larger than the ordinary run of epithelial cells and they showed appearances which simulated those found in carcinoma.

Dr WOODHEAD said that he felt somewhat disappointed that it had not been possible to adhere to the original pro-

gramme sketched at a former meeting of the Society. He felt that for several reasons it would have been more satisfactory had the sets of specimens (that formed the texts for the remarks of the various exponents of different views) been submitted to the Morbid Growths Committee. There had been demonstrated before the Society, and not of course under the most advantageous conditions, specimens on which those who were interested in the matters at issue were asked to express a definite, if not a final, opinion. For himself, he had to thank Mr Jackson Clarke for putting his specimens and time at his (Dr Woodhead's) disposal in order that he might have a clearer idea of what Mr Clarke's views were and how they were supported by the specimens he had prepared and demonstrated. He thought Mr Clarke's assertion that Russell's bodies were nothing but the result of degenerative changes was far too sweeping. It was undoubtedly the case that Russell had not differentiated sufficiently between the structures he had stained and described, some of which, no doubt, were the parasitic organisms described by Soudakewitch, Ruffer, Walker and others, although others were nothing more than altered, degenerated cells and in some cases red blood corpuscles, but Russell undoubtedly had recognised as parasitic certain structures which, in this country at any rate, had previously been passed over or their importance and characteristic structure neglected. He himself had not fully recognised how much of accuracy there was in Russell's work, nor probably had Russell himself until the appearance of Soudakewitch's paper, followed so rapidly by the exquisitely demonstrative preparations of Ruffer and Walker. Mr Clarke told them that Malassez, who after Thoma was one of the first to take up the subject, was not fully convinced until he had seen Damer's work, and it was possible that many of the members of this Pathological Society were in a similar state of mind (some might still remain in that condition) until they had seen the beautiful specimens demonstrated by Drs Ruffer and Plimmer at the last meeting. It had been remarked that pretty specimens were all very well, but that, after all, structural detail was the main thing to be sought in any histological specimen. He should be the last to contradict such a dictum, but he might add that, without very perfect fixing and hardening and accurate differential staining methods, by which alone pretty specimens could be ensured, no good detail could be brought out, and it was only as our methods had become perfected to their present condition that our recent more accurate knowledge of cell and nuclear structure had been obtained. The very fact, however, that we now often saw appearances with which we had hitherto been unfamiliar was a too frequent source of error, as a result of which nuclear structures or various degenerative changes had often been mistaken for parasitic structures, whilst, on the other hand, he had a not very limited experience of an equally common mistake—the confounding of parasites imperfectly fixed and stained with nuclei. Now this was important, for several observers, who for long were unable to satisfy themselves that they had seen one of these parasites, on going over their specimens again—he himself had been in this position, so he felt he could speak with more certainty—were satisfied that parasites were undoubtedly present. All this must be carefully borne in mind in dealing with this question. The other morning he had received a note and a paper from Mr Gustav Mann, assistant to the Professor of Physiology in the University of Edinburgh, certainly an expert in the preparation of histological specimens, both vegetable and animal, who pointed out that he had been able to demonstrate in many of his specimens nuclei which he could not distinguish from the parasitic protozoa of the epithelial cells of cancer as described by Drs Ruffer, Walker and Galloway. The nuclei, as figured by him, were certainly very like those protozoa with the appearances of which we are now familiar, but on comparing the two sets of structures it would be seen that there were essential points of difference as regarded their relation both to the cell protoplasm and to structures which could be recognised as ordinary nuclei. Of course it had been objected that the radiating streak in the parasitic bodies was not peculiar to them, and certainly any one who had carefully examined the lines radiating from the nucleus of an epithelial cell of the cuticle as a centre through and beyond the protoplasm to form the prickles with which every histologist was familiar would accept this statement as accurate, but he would reserve to himself the right of arguing that in the organised parasitic cell there must be several features which it had in common with other animal cells, though they were built up into a highly organised organ or tissue. We must expect to find certain points of

similarity, otherwise we should not be justified in looking upon the parasite as an animal cell, or perhaps even as a living cell at all. We could not insist too strongly, then, that now we had such good histological methods at command we must not be satisfied with impressionist pictures or specimens which showed not what might actually be brought out, but what the investigator might feel compelled to read into them. As an example of what was too commonly accepted, the case of molluscum contagiosum might be instanced. Parasites had been described as present in this condition, and no doubt in many cases there were bodies which had not previously been described, but he for one had never been able to convince himself that the so-called parasites were not epithelial cells, in which certain changes, degenerative, no doubt, had taken place. Mr Clarke had referred to Sjöbering's illustrations, which by many workers had been described as too diagrammatic—a criticism which at one time he would have willingly endorsed, but now he should be very careful indeed in making such a comment, as, after seeing the various specimens recently prepared and demonstrated by Dr Ruffer and Mr Plimmer, he was prepared for much in the way of diagrammatic specimens. It would scarcely be necessary for him to repeat what had already been said concerning the pseudo parasites, included and degenerated cells, irregular mitoses and the like, but he did wish to point out that when he spoke of these parasites more than a year ago he was wishing to draw attention to the analogous process in the liver of the rabbit and the kidney of the snail, and in describing the parasites as oocidial he wished to draw attention to the process rather than to the specific and definite form of the parasite, which, as it had only just had special attention drawn to it, was still undescribed in detail, and not only were the methods of development and reproduction still unknown, but its very structure was as yet imperfectly made out. It was, he confessed, somewhat rash to draw an analogy which should only have been suggested. He could not accept it as yet proved that we knew anything about the mode of reproduction or method of action of these parasites, and after a careful examination of some of Mr Clarke's specimens under the favourable conditions afforded by Mr Clarke's kindness he was still unable to accept his conclusions. In the first place—and he was sure both Mr Clarke and the members of the Society would accept his criticism in the spirit in which it was offered—he had not been able to make anything out in these specimens for which some other explanation than that they were parasites could not be offered. For instance, he believed that what Mr Clarke described and demonstrated as ripe psorosperms—using that term as Mr Clarke himself used it—in an epithelioma were what had already been described by numerous observers, but which, so far as his experience would allow him to speak, were merely included and degenerated cells—an explanation of all "parasitic" bodies offered by Welch. As to the ripe "psorosperms" in connexion with sarcoma of the femur shown at the last meeting, he had again to join issue with Mr Clarke, the plasmodial form described by him was a plasmodium, but it was of that kind known as the giant-cell of the myeloid sarcoma, which so frequently contained not only blood pigment, but also red blood corpuscles in various stages of degeneration, the larger size on which such stress was laid being the result of the degenerative changes that ensued on the death of the corpuscle. He himself had described these swollen red blood corpuscles some twelve years ago. Again, in another sarcoma in which Mr Jackson Clarke described masses of ripe psorosperms, he believed that these were simply areas of degenerated sarcoma tissue—such areas as were common in every sarcoma, especially when hemorrhages were scattered through them. The "spores" that were found near these areas, and also in the neighbourhood of the degenerating epithelial cells in the epithelioma, could not, to his mind, be in any feature different from leucocytes of various forms such as were invariably found in the region of devitalised tissues. It would, in any case, be necessary to bring forward much more evidence than had up to the present been offered to induce most histologists to accept them as spores of sporozoa rather than as phagocytic leucocytes. It would not do for us to argue from the general to the special in this matter, and it was certainly most dangerous for us to say that the parasite which we assumed set up the cancerous proliferation resembled, as regarded life history, methods of multiplication, structure and function, those found by Mr Clarke in the ureter or those described by other observers in the kidney of the snail or the liver of the rabbit. These two latter differed in most marked features and essential details from one another, and

we should expect that the parasites in other positions might present equally distinctive characters. Whoever had right on his side in this matter it must be recognised that the protozoa described by Dr Ruffer and Dr Galloway and their colleagues were essentially different from those described by Mr Clarke. Much valuable work on the parasitic origin of cancer had been brought before the Society. In 1877 Messrs Ballance and Shattock indicated the nature of what they thought might be the *causa causans* of the conversion of benign into malignant epithelial cells and, so far, their indications appeared to have been correct. Then in turn Russell, Bowlby and Hutchinson, Delépine, and D'Arcy Power (members of this Society) had all contributed to our knowledge, and, lastly, came this interesting discussion. He was yet far from convinced that Mr Clarke had right on his side. His senses would not go along with him in that direction, although Mr Clarke's specimens that evening were infinitely better demonstrated than they had been on any previous occasion. It might be that the speaker was more familiar with the parasites described by Dr Ruffer and others but in these there was something which he could grasp and follow out, whilst, on the other hand, he felt that satisfactory explanations, other than that the bodies described were parasitic, might be offered of all the appearances Mr Clarke had set before them.

Mr BALLANCE exhibited for Mr Shattock and himself micro-photographs showing certain appearances observed by them in Incubated Scirrhus of the Breast. In May, 1888, Mr Shattock and he read a paper before the Society on the same subject and they had lately repeated the observations. The appearances consisted in budding of the chromatin of certain elements in the tissue, and though seen apart from incubation they were especially evident after it. Their present experiments consisted in incubating portions of scirrhus for different periods in sterilised milk and glycerine at the room temperature. After a few days the nuclei of the epithelial cells ceased to take nuclear stains, but there remained certain elements which stained intensely with logwood, and green with Biondi's reagent, in this resembling nuclear chromatin. The elements were surrounded by an unstained envelope, and the stained centre underwent a process of fission and budding whilst after six weeks' incubation the section was remarkably full of them. Whatever their nature, they clearly underwent multiplication after the death of the other elements. Professor Sherrington had made the observation that in potassium oxalate the white blood-corpuscles would remain alive for certainly twenty four days. Whether the bodies in question were leucocytes or some form of connective tissue cell or whether they were parasitic in nature the authors at present left for further observations. In their previous paper they had suggested a comparison between the extrusion of nuclear chromatin in carcinoma and the extrusion of the polar bodies preparatory to fertilisation of the ovum and of the seminal granules from the spermatozoa, each form of cell being originally as Balfour had suggested, hermaphroditic, and they had also conceived of a hypothetical protozoon in some way conjugating with the tissue cells. Stricker had advanced the idea of sexual differences in the body cells, and more lately Auerbach had endeavoured to show that the cyanophile component of nuclear substance was male and the erythro-philic female, for in osseous fishes and batrachia the ova took the red stain the head of the spermatozoon the blue. In sections of carcinoma they had seen bodies containing a red and a green nucleus under Biondi's reagent, the red corresponding in general appearance with the nucleus of the body described by Soudakewich and Drs. Ruffer and Walker. Dr Ruffer had also figured the nucleus of the parasite as blue, though this was exceptional. It remained for investigation whether a sexual process of some kind did not obtain either in the parasite itself or between the parasite and tissue cells. Whether the multiplying bodies the authors had found in incubated scirrhus were in any way related to the parasite, as this was described by Soudakewich Dr Ruffer and others, they were at present unable to say.

(To be continued.)

OTHER METROPOLITAN MEDICAL SOCIETIES

EPIDEMIOLOGICAL SOCIETY.—A meeting of this Society was held on Feb 15th Dr J F Payne, President in the chair.—Mr R. D. R. SWETING read a paper on Post

Scarlatinal Diphtheria. He said that an analysis of the reports of the fever hospitals of the Metropolitan Asylums Board for the four years 1884-87, before cases of diphtheria were received, and for the four years 1889-92, after this disease was admitted, showed that during the latter period the incidence of post-scarlatinal diphtheria had enormously increased, and that it had become terribly fatal. The incidence had been greatest at the Western Hospital and least at the North-Western Hospital. At the former, owing to the extent to which the drafting away of convalescents had been carried out, the aggregation of acute cases alike of scarlet fever and of diphtheria, had been greatest the North Western Hospital presenting the reverse conditions in every respect. There could then be little doubt as to the connexion between post-scarlatinal diphtheria and aggregation of acute cases. At the Northern Convalescent Hospital the incidence of post-scarlatinal diphtheria had been pretty uniform during the whole period of its existence—viz., 1867-92—the admission of primary diphtheria in 1889 having apparently made but little difference. It was remarkable that this complication usually occurred at a late period of convalescence, in more than half the cases after the lapse of four weeks from admission. The monthly prevalence, the age incidence and fatality all showed that the disease was true diphtheria and not a mere phase of scarlet fever. Post-scarlatinal diphtheria had begun to appear at the new convalescent camp at Gore Farm, although no cases of simple diphtheria were received there. In analysing the cases at the several hospitals it was found that very few could be explained by infection from outside or by concurrent incubation or by personal infection from cases already in the wards, nor could the condition of the wards or defects of drainage or of ventilation be adduced as causes. It did not appear to be attributable to faults of administration, though from the absence of complete separation of the medical staff these could not be altogether excluded. He suggested that possibly under the influence of aggregation the poisons of scarlet fever and diphtheria acquired an altered character and increase of potency rendering them more diffusible or perhaps even transmissible, in other words that the line of demarcation between the two being feebly marked the efficient cause or specific poison of scarlet fever must under certain environments be transmuted into that of diphtheria.—Dr WILLOUGHBY said that under the circumstances there could be no doubt that the disease in question was true diphtheria and not a mere complication of scarlet fever, but, though a believer in evolution in the remote past he was loth to admit transmutation and would rather compare the apparent *de novo* origin of these cases with that of erysipelas. Both were facultative parasites or, as he preferred calling them, extra corporeal contagia, widely diffused and only needing for their development a suitable soil, which diphtheria found to perfection in the post-scarlatinal throat.—Dr THORNE THORNE, whilst fully recognising the receptivity of such throats to the poison of diphtheria, as Dr Greswell had so forcibly shown doubted the ubiquity, as Dr Willoughby had expressed it, of the diphtheritic microbe, for during seventeen years out of twenty, during which over 6000 cases of scarlet fever had been treated in the London Fever Hospital, there had been none of diphtheria, and at St Thomas's Hospital, where 383 cases of diphtheria and 134 of scarlet fever had been treated in the same pavilion but in absolutely isolated wards there had been only one instance of diphtheria in a fever patient. He believed errors in administration to be the whole explanation.—Dr CAIGER said that he thought it rather a question of environment and weather conditions for at the South Western Hospital they had had no cases amongst 2000 cases of scarlet fever in 1891 and only eighteen in 1892 under still greater pressure, but there had been a good deal at Winchmore Hill as well as at Gore Farm, no diphtheria cases being received at either place.—Dr MCCOMBIE defended the administration of the hospital observing that few children were admitted into the London Fever Hospital and that the mortality in post-scarlatinal measles also was very high. He doubted the great influence ascribed to aggregation and had admitted cases of post-scarlatinal diphtheria which had been developed in the home.—Dr HORWOOD stated that on each of the two occasions in which post-scarlatinal diphtheria had broken out in the London Fever Hospital serious defects in the drains had been detected the disease disappearing as soon as these were remedied.—Dr MATTHEWS considered that the site and surroundings were the most efficient factors, adducing the case of Gore Farm, where no diphtheria, as such, was ad-

mitted, but where in the male block, situated on a dry soil, one case in seventy five, and in that for females, on a damp and lower site, one in twenty eight had been attacked.—Mr Shirley Murphy, Dr Goodall and Dr K. McLeod having also taken part in the discussion, Mr Sweeting replied.

HARVIAN SOCIETY—The meeting on Feb 16th was devoted to the exhibition of specimens, Mr Malcolm Morris, President, in the chair.—The PRESIDENT showed a case of Pityriasis Rubra in a woman aged twenty six who came under his care ten months ago with a general eczema. She was admitted to St. Mary's Hospital, and whilst under treatment the present condition developed. There was considerable desquamation, and the hair and nails came out. This was accompanied by pyrexia and an extremely rapid pulse, the legs became cedematous, anorexia and sleeplessness were prominent, there was no albuminuria. At present the hair of the head is about four inches long and the nails have grown. There is still some desquamation and the whole surface is red, there is no pyrexia. The constitutional symptoms have all abated and there is general improvement. The President also showed a case of Lupus Erythematosus in a girl who had been under his care for fourteen months. She was treated with internal remedies for six months with no effect, external remedies were afterwards tried with considerable benefit. He pointed out how difficult some varieties of this disease were to cure from the depth to which the sebaceous glands were implicated.—Mr ROUGHTON showed a patient who, when vaulting the table from the "storming board" in a gymnasium, alighted on the edge of the mat, twisting his foot inwards. The leader of the gymnasium "put his foot back," and the patient was then brought to the Royal Free Hospital. Fracture of the astragalus was suspected, probably through the external part of the head.—Mr ATWOOD THORNE showed a case of Consolidated Aneurysm in a man aged forty six, a plasterer, who was admitted into St. Mary's Hospital, under the care of Mr Silcock, on Dec 20th, 1892. There was then a large pulsating tumour to be felt on the right side above the outer two thirds of the clavicle, below the clavicle for the same distance, and in the axilla. There was also dulness in the outer part of the upper two intercostal spaces. The right radial pulse was somewhat delayed, was fuller and more compressible than the left. As the case was considered to be one of aneurysm of the axillary and the third part of the subclavian arteries, an attempt was made to ligature the first or second part of the subclavian. However, on dissecting down to the artery above the clavicle the first part of the subclavian was found to be affected, the artery here being about an inch and a half in diameter. The idea of ligaturing the artery was consequently abandoned and the wound closed. On removing the dressings two days later the wound was found to be septic. The pulsation in the subclavian and axillary regions diminished day by day and the pulse at the wrist was gradually lost. Mr Thorne then demonstrated the case. The wound was quite closed. There was slight pulsation in the parts previously affected, no pulsation in the radial and very slight pulsation in the ulnar at the wrist. An opinion was expressed that the septic change in the wound had some influence in the alteration of the aneurysm.—Dr BOXALL showed a patient aged forty-one who had a well defined hard mobile swelling in the right ovarian region. By internal examination the growth was found to spring by a short pedicle from the right side of the fundus, the uterus itself was in the normal position and was not enlarged, the sound passing barely three inches in the normal direction. She had one child, at the eighth month, three years and a quarter ago, and whilst carrying had noticed an unusual swelling in the abdomen. At the time of delivery the growth was of such a size that her medical attendant at first thought there might be another child, and after consultation expressed the opinion that she would be dead in eighteen months if it were not operated upon. She has been under observation as an out-patient at the Middlesex Hospital since six weeks after delivery, and from that time to this has never experienced the slightest inconvenience from the presence of the tumour. The points to which particular attention was directed are (1) the variation and, on the whole, diminution in the size of the tumour (to the extent of one inch both in the longest and shortest measurements), though no active treatment has been pursued, (2) the possibility that a tumour of this size (foetal head) might slip into the pelvis, there become impacted and give rise to urgent pressure symptoms. This is here prevented by the short attachment to the fundus and by the fact that the uterus maintains its normal position and acts as an

efficient support. Comment was made upon the difficulty of distinguishing at the time of delivery such a tumour from an ovarian cyst.

SOCIETY OF MEDICAL OFFICERS OF HEALTH—A meeting of this Society was held on Feb 20th, Mr Shirley F. Murphy, President, in the chair.—Dr REGINALD DUDFIELD read a paper on the Sanitary Certification of Houses, as practised by the local authority at Eastbourne, and, so far as he knew, at no other town except Teignmouth, comparing the requirements with the recommendations of the model by laws of the Local Government Board, THE LANCET Commission of last year and Dr Farquharson's Bill, all of which came short of these in stringency. The connexion of the drains of new houses with the older ones was made by the workmen in the employment of the corporation directed by the borough engineer, for house drains &c the building surveyor was responsible, whilst the medical officer of health and his inspectors took cognisance of all old—i.e., existing—buildings. This division of labour worked well, and the system of inspection, registration and certification had grown up by degrees and was still being improved. The certificates were issued only in respect of hotels and lodging and private houses rented at £50 and upwards, and amongst the conditions insisted on were the interception and ventilation of the drains, disconnection of waste and rain water pipes, ventilation and anti siphoning of soil pipes, separate water service for w.c.'s, pan closets being prohibited, and the testing of all drains and soil pipes, the former by water, but without artificial head or pressure, the latter by driven smoke. The minimum fall of house drains allowed was $1\frac{1}{2}$ in 10. This was, he remarked, unusually great, but, on the other hand, the only water pressure applied was that to which the pipes would be actually subjected—viz., that of the gulleys themselves. A register was kept of all arrangements and tests applied to them, and the certificate, which testified to the condition at the date of inspection only, was valid for one year. New houses were certified when finished if desired, old ones only on application from owner or occupier, and after the drains had been opened up, tested and, if found defective, relaid throughout. He hoped to institute a system of periodical reinspection before long, but already the favour with which certified houses were regarded by visitors and even the opposition at first made by house agents and some owners were evidence of the advantages accruing therefrom. The expense rarely devolved on the tenant, and very often notices for the "abatement of nuisances" were followed by requests for certification, thus ensuring the thoroughness of the work done. He was strongly of opinion that the sanitary authority should alone grant certificates and not accept them from irresponsible persons, as under Dr Farquharson's Bill, which would, he believed prove a failure.—Professor CORFIELD feared that should such a practice as that described by Dr Dudfield become general, the authorities would be exposed to actions at law if, in the event of typhoid fever occurring in a certified house, an expert should be able to discover any defect in a drain, and Mr Keith Young was of the same opinion, though fully appreciating the value of the register to persons seeking houses.—Dr L. PARKES thought that the system though excellent in itself and adapted to places like Eastbourne could not be extended to London and similar large towns but felt that the site, ventilation &c should also be taken into account.—Drs GIBSON, KENWOOD and WILLOUGHBY discussed the ventilation and testing of drains, and Dr DUDFIELD, replying to Dr Corfield, pointed out that the certificate guaranteed the soundness of the drains at the time of inspection only, so that no action could be for anything that might occur subsequently.

PROVINCIAL MEDICAL SOCIETIES

PLYMOUTH MEDICAL SOCIETY—At a meeting held on Feb 18th under the presidency of Mr Leah (Stonehouse), Mr F. EVERARD ROW read a paper in which he reviewed the Common Objects of the Hospital Ward, commencing with varicocele. Treatment of this condition was advocated by the excision of a portion of the veins between ligatures, with subsequent shortening of the cord. For varicose veins Mr Row recommended ligation of the vein at several points, and for hæmorrhoids considered the ligature equal to other methods. Spasmodic and fibrous strictures of the male urethra and the subject of radical cure of hernia,

acquired and congenital, were discussed, preference for Mitchell Banks method in the latter cases being expressed. The flap-splitting operation for ruptured perineum was advocated. A consideration of the use of drainage tubes concluded this eminently practical paper, in the discussion following which Messrs Jackson, Bulteel, Woolcombe and Swain joined.—A clinical evening was held on March 1st, at which Dr Fox showed a case of Diabetes with marked Choroiditis.—Mr WOOLCOMBE brought forward a man aged fifty four with Paralysis of the Right Arm due to Lead Poisoning and left facial paralysis of uncertain causation, which was now improving, the patient also had an exostosis growing from the humerus near the musculo-spiral nerve. Mr Woolcombe also exhibited for Mr Lucy a boy aged four wearing a boot made by a local bootmaker also the subject of Syne's amputation. Mr Woolcombe demonstrated a uterus with a large fibroid mass attached removed by hysterectomy. During operation the thinned and drawn up bladder was twice opened and sutured, and an excellent recovery resulted.—Dr WILLOUGHBY showed a Carneous Mole passed during the eighth week of pregnancy.—Mr Row showed a Pocket Midwifery Case made from his designs by Messrs Allen and Hanburys.—Mr WHITEFORD exhibited a photo of a Urine-testing Table designed by Mr R. Stanley Thomas and now in use in the wards of the South Devon Hospital.

SHEFFIELD MEDICO CHIRURGICAL SOCIETY—At the meeting on Feb 23rd, the PRESIDENT (Mr Simeon Snell) introduced two cases of Hemianopia—both men. In one there was word blindness also, in the other right lateral hemianopia was followed by loss of sight on the remaining half of the retina, with the exception of a small area on the left side of the fixation point. Mr Snell remarked on the pupil reaction in these cases and said that in the first case, where the lesion was a cortical one, the pupil responded to light, whilst in the second the 'inaction' was demonstrated in all parts of the retina except over the central part, which was intact, and where the pupil acted to light thrown upon it. This would indicate that the lesion was on the peripheral side of the corpora quadrigemina.—Mr DALE JAMES showed a case of Exfoliative Dermatitis. The disease began as seborrhœic eczema when the patient now aged ten years was three months old. The case illustrated the change of type that frequently takes place in very chronic eczema and also Unna's contention that general exfoliative dermatitis is commonly derived from seborrhœa of the scalp.—Dr GEORGE WILKINSON showed for Dr CLAPHAM two cases from the Sheffield Public Hospital. They were sisters and had worked with lead. Both were affected with rapid clonic spasms on rising to the erect posture, on walking and also to a certain extent on performing other movements. The knee-jerks were exaggerated there was a peculiar affection of speech, a dull mental condition and all actions were done very deliberately. The diagnosis of the cases between saltatorial spasm, myoclonus multiplex, insular sclerosis and hysteria was discussed.—Mr GAERARD showed 1 oz. of Water removed by lithotomy and a Uric acid Calculus $2\frac{1}{2} \times 2 \times 1\frac{1}{2}$ in. and $3\frac{1}{2}$ oz. in weight removed by supra pubic lithotomy.—Mr FRANK HARRISON showed an extensive collection of Dental anomalies.—Dr. Ruxton and Adair showed several Brains prepared by Guicomini's process illustrating cerebral softening internal hydrocephalus, general paralysis of the insane &c. They also showed microscopic specimens of nuclear vacuolation of the cells of the second layer of the cerebral cortex from cases of epilepsy spider cells from cases of alcoholic insanity fuscous degeneration of nerve cells and slides illustrating the existence of marked changes in the peripheral nerves of cases of general paralysis of the insane. All the specimens were described, and the microscopic ones were illustrated by photo-micrographs.

Reviews and Notices of Books.

The Hygiene Diseases, and Mortality of Occupation. By J T ARLIDGE, M.D. London Percival and Co 1892.

THIS valuable work by Dr Arlidge is an expansion of his Milroy Lectures delivered in 1889 at the Royal College of Physicians. We owe the author an apology for having so long delayed any notice of this book, a delay which was caused by unforeseen circumstances and in no way attributable to any want of appreciation of its great value. Social questions rightly occupy a large amount of public attention at the present time, and in order that we may arrive at just conclusions concerning the many social problems with which legislators and public men are constantly confronted the first thing necessary is exact information. The excellent work of Mr Charles Booth on the 'Life and Labour of the People' has put us in possession of a large number of facts which are indispensable for those who wish to arrive at any just appreciation of the conditions of life which have to be encountered by different classes of the community and the work which is the subject of the present notice is in many ways complementary to that of Mr Booth and supplies statistical and scientific matter which serves to complete our view of many social problems. Dr Arlidge's work should be welcomed by legislators and philanthropists as well as by the members of the medical profession, whose duty it is to be specially acquainted with those causes which affect the health of the different sections of the industrial community. Dr Arlidge is no mere statistician, nor is he merely a compiler of facts collected by others. He has opinions of his own—opinions formed during a long and honourable professional career which has given him singular opportunities of becoming practically acquainted with the subjects of which he treats. The influence of machinery on the health of the people is thus alluded to on p 25—

The expansion of manufacture by the agency of machinery is the most remarkable feature of the present age and every year the simple handicrafts are reduced in number and profoundly modified in character. It leads to the extension of associated labour in factories and to an astonishing subdivision of work. One result of this latter circumstance is an increased monotony of occupations. In the boot and shoe trade, for instance, whilst the machines in use deliver the workman from the cramped and unhealthy position enforced upon his forefathers and from the chest pressure caused by the last they deprive him of whatever satisfaction might be felt in making and turning out entire a boot or shoe and cause him to expend his technical ability in dreary monotony on making only one portion or a stitching two parts together. In fact it may truly be said of machinery that it reduces those who use it to the position of a part of itself. The man is transformed in a greater or less degree, into an accessory machine, and even in this humble position his utility is perpetually encroached upon by the invention of new automatic movements. And, generally speaking it may be asserted of machinery that it calls for little or no brain exertion on the part of those connected with its operations, it arouses no interest and is wearisome by monotony. Machinery consequently has nothing in it to quicken or brighten the intelligence, though it may sharpen the sense of sight and stimulate muscular activity in some one limited direction."

There are some pertinent remarks on the fashion of the present day to seek 'genteel' employment in preference to handicrafts and to regard hard manual work as less noble than those feeble manual employments which necessitate the use of the pen although it must be admitted that the carpenter who really produces some household appliance or piece of furniture really makes more use of his intelligence than the man who sits all day upon a stool laboriously copying at so much a folio.

"The teaching of statistics," says Dr Arlidge, "is that trades requiring strong and those demanding moderate

LONDON SANITARY PROTECTION ASSOCIATION—Dr Bristowe presided on Monday last at the twelfth annual meeting of this Society when the report of the Council for the past year was read. A very favourable account was given of the work accomplished, 535 houses having been visited, of which 68 per cent. were adjudged to be in a more or less bad condition. Amongst the buildings inspected were sixteen hospitals, schools or other public institutions. In view of the probability of the Association sharing in the Berridge legacy it has been proposed to render the twelve years experience derived from the operations of the Society available by means of lectures, publications &c.

exertion are far and away more healthy than others demanding little or no bodily effort. And all this is in harmony with what physiology proves—that the exercise of organs, and especially of the muscular system, is a pre requisite to health and preservative of life."

As a necessary corollary to the above, Dr Arlidge gives it as his opinion that if there is to be any interference with the hours of labour it is not the more laborious and more healthful employments which should be first considered, but rather those industries which necessitate unwholesome work indoors, and which really deprive the artisan of what our author rightly styles the pre requisite of health.

The fourth chapter of this book is devoted to a classification of employments, non traders, traders, artisans &c., with their subdivisions, and the reader who wishes for information as to the diseases which are especially prevalent in any class of the community will here be provided with a storehouse of facts which have been collected with equal industry and judgment. Chapter five deals with the Pathology of Dust Inhalation, and the various employments which necessitate the inhalation of dust or noxious vapours are here passed in review. The amount of information contained in these last two sections of the work is very great indeed, and there is scarcely an industry, certainly no industry of any importance, of which the chief facts connected with its processes, and especially the injurious parts of such processes, are not given. These portions of the work do not lend themselves to quotation in a review, and it only remains for us to say that, having gone carefully through the book, we can confidently recommend it as a valuable work of reference to all who are interested in the welfare of the industrial classes.

Contributions to the Physiology and Pathology of the Mammalian Heart. Philosophical Transactions of the Royal Society. By Dr C S ROY and Dr J G ADAMI. 1892.

A PAPER occupying 100 pages of the current volume of the Philosophical Transactions by Drs Roy and Adami, entitled "Contributions to the Physiology and Pathology of the Mammalian Heart," gives a careful description of methods, instruments and results, the outcome of ten years' study, and will be welcomed by everyone interested in the mechanics of cardiac contraction. By means of the cardiometer—an instrument on the principle of the volume recorders or oncographs so successfully employed on the spleen and kidney—the authors took prolonged observations of the systolic discharge from the two ventricles and by means of an "automatic counter" they recorded the rate of total output. A third instrument—the myograph—served to record the changes of length of any desired portion of the ventricles, thus sampling the changes of their total circumference. These bare indications must suffice to indicate the means of approach devised by the authors, it is not possible to describe them intelligibly without figures. One of the most important results established is that normally the ventricles do not become completely empty at the end of systole, and we are told that with "increase of aortic pressure there is, other things being equal, an increase in the amount of residual blood." The actual quantity of this residual blood, under various circumstances, as compared with the quantity expelled, in systole—data which must have been frequently under observation—cannot, however, be found, nor are any of the cardiometric tracings supplied with a scale so as to enable us to form more than an approximate estimate of the volume-value of the lever excursions. Judging from the tracings, the systolic discharge (in small and medium sized dogs) appears to have been between 5 and 10 cc.—i.e., lower than the values observed by Stolnikow. A large number of the authors' experiments relate to vagus effects—e.g., they show that with slower beat there is increased volume ($\times 2$, $\times 3$ or more), yet a diminution of total output (30 to 35 per cent.) From other experiments (chiefly by the myo cardiographic method)

we learn that the auricle is under closer subjection to vagus control than is the ventricle by reflex, as well as by direct excitation of the nerve, whereas the auricles (p. 220) may be arrested for hours, the ventricles soon resume contractions with an independent rhythm—indeed, we are informed that the vagus neither weakens the ventricular contraction nor exerts upon it any antitonic effect (pp. 224, 227). Moreover, muscarin arrests the auricle, whilst the ventricle goes on independently. The augmentor effects occasionally to be observed by vagus excitation came under the authors' observation, but are not believed by them to be due "to the presence of augmentor fibres such as are contained in the vagus of the frog," and the supposition is made that they may act by producing dilation of the coronary arteries. They are met with only in ill conditioned animals. Evidence is also offered of the existence of cardiac fibres from the stellate ganglion, causing weakening of the auricular and ventricular contractions (p. 247). These may "possibly" be constrictors of the coronary arteries, and the authors themselves lay particular stress upon this word "possibly," having no evidence to offer in support of the supposition. Another section is devoted to the study of the augmentor nerves, and in conclusion the authors discuss the significance of the cardiac nerve mechanism from the teleological standpoint.

The Microscope its Construction and Management. By Dr HENRI VAN HEURCK, Professor of Botany at Antwerp. English Edition, re-edited and augmented from the Fourth French Edition. Translated by WYNN E. BAXTER, F.R.M.S. With Three Plates and upwards of 250 Illustrations. London: Crosby Lockwood and Son. 1893.

THIS very handsomely got up volume is much more than a mere illustrated catalogue of microscopes and microscopic apparatus, for it is written by an author who has himself made considerable improvements in the construction of various accessory pieces, such as the "comparing ocular," and the "achromatic transformer," and in the application of electricity as an illuminant. As Mr Baxter remarks, this work must necessarily be of interest to all who devote serious attention to microscopic work as a means of comparing the continental views and modes of thought with those of their own and other countries. The first chapter is introductory in its character, and deals with reflection and refraction of light, spherical and chromatic aberration and the general construction of the simple and compound microscope, the second chapter gives Professor Abbe's theory of microscopical vision, and is followed by a paper written by Mr J. W. Stephenson, giving a series of experiments in support of Professor Abbe's theory, both of which are interesting. The invention of the microscope is ascribed to Zacharias Janssen of Middelburg, about the year 1590, and the author describes briefly the several parts of an ordinary compound microscope. He then discusses the "objective," and holds that the best test of definition is still the nineteen band test plate of Nobert, though it may be replaced by the graduated diatom test of Möller and the median nodule of the pleurosigma, which presents a small ball terminated by an excessively delicate thread which is lost in the raphé. This latter is stated to be a hitherto unknown and excellent method, well adapted for a photographic test. The "ocular" is then described, with its varieties, including Huygens' and Ramsden's orthoscopic, compensating and projection oculars. An immense number of excellent engravings show the construction of the stage and stand of the great microscope makers, such as those of Zeiss, Leitz, Ross, Powell and Lealand, Beck, Bénèche, Reichert, Bèzu and Hauser, Hartnack, Chevalier, Nacher, Crouch, Watson and others. Many of these instruments are designed for special purposes. Those who are interested in photomicrography will find a chapter devoted to that subject. The author considers that if sunlight be used a heliostat must be

employed, and that the simplest, most practical and least expensive heliostat with which he is acquainted is that of Prazmowski, which is supplied in Paris by Bézu, Hauser and Co and in Potsdam by Hartnack. The last section of the work gives general rules for preparing microscopical objects, followed by a short history of the microscope and by a bibliography. The work reflects credit alike on the author, the translator and the publishers.

LIBRARY TABLE

Traité Élémentaire de Physiologie Par J. V. LABORDE, Directeur des Travaux Pratiques de Physiologie à la Faculté de Paris. 1ère Partie. Pp 387 avec 155 figures. Paris Société d'Éditions Scientifiques. 1892.—M. Laborde's treatise commences with a brief but interesting chapter on the technique of operations on the frog, guinea pig, rabbit and dog, describing and illustrating the dissections requisite for the exposure of the heart, sciatic nerve and artery, external saphenous and jugular veins, the carotid artery and vagus in these animals. This section of the work stands therefore in relation to physiology as a dissector does to anatomy, giving an experimental demonstration of the facts stated—such, for example, as the action of curare, the proofs of recurrent sensibility in the motor roots, the phenomena of the degeneration after section of the spinal nerves—instead merely of the dry facts. M. Laborde does not think that the evidence at present advanced in regard to the capability of the conduction of impulses in either direction by every nerve fibre is valid. The evidence rests on Vulpian's experiment of dividing the lingual branch of the fifth and the hypoglossal nerves where they are in juxtaposition and effecting a suture of the central end of the fifth with the peripheral end of the hypoglossal. It is found that after the lapse of some months stimulation of the lingual above the point of union causes contraction of the muscles supplied by the hypoglossal. The defect of this experiment, as Vulpian himself pointed out, is that the chorda tympani, the fibres of which run in the lingual, is a motor nerve, and if this be cut no motor effects are observed. The second piece of evidence is that adduced by Paul Bert to the effect that the extremity of the skinned tail of a rat implanted in a wound in the back and divided at the root becomes attached, and after some months recovers its sensibility, but the objection here is that it is quite possible for union to have taken place between the sensory fibres of the tail and those of the skin of the back. M. Laborde thinks the only prospect of settling the question is by effecting union between the anterior and posterior roots of the second spinal nerve of the cat, in which animal the ganglion of this nerve is situated outside the spinal canal. He states that he is himself pursuing this inquiry. Continuing this subject, he gives the results of division of the several columns of the grey matter of the spinal cord, and the laws of reflex action. He considers that the latter can best be shown in mammals by experimenting on kittens. If in these animals the calvaria be removed and the cerebrum be cleared away by a stream of hot water till only the pons Varolii is left the animal will remain alive for nearly a day and all reflex actions can be well demonstrated upon it. After a careful exposition of the various theories that have been advanced—some on the basis of experiment, some on anatomical grounds and others again, on pathological ones—in regard to the use and functions of the cerebellum, M. Laborde believes that the most correct view is that it is an organic centre of coördination and regulation of voluntary movements. Its normal activity is essential to the preservation of the harmony and the equilibrium of these movements and to enable them to work efficiently and surely together. The wide subject of the cerebrum and its functions is well and fully given. Altogether the work fairly

represents the present standpoint of modern physiology, though we should like to have seen some notice of recent English work, such as that of Dr Gaskell and Dr Sherrington.

Royal Road to the British Pharmacopœia By WALTER F. CLAYTON. London. Harmer and Harley. 1892.—In the introductory remarks the author commends his mnemonics to pharmaceutical, medical and other students, and he wishes his rhymes to be so thoroughly committed to memory that they may be recalled "and repeated mechanically," "without effort or apparent application of thought." He does not indicate to whom they are to be "repeated mechanically," nor what result might be expected to follow such lack of "application of thought." The doggerel verses are very much of the usual type, abbreviations abound, and scanning is not always an easy matter. No doubt, if studied first in conjunction with the Pharmacopœia, these mnemonics might be useful to some students, but they leave many important official preparations untouched and appear to lay stress upon many which no one could possibly be expected to commit to memory.

Seventy Years of Life in the Victorian Era By A. PHYSISIAN. London. Fisher Unwin. 1893.—This is a pleasant, gossip narrative of the experiences of one who has seen a good deal of the world ashore and afloat. Its descriptions of foreign parts are interesting and, without any attempt at literary display, the author has managed to import into his diary (for the record assumes this form for the most part) a considerable amount of information, useful as well as attractive. Pecuniary difficulties hampered the early career of the author, but friends seem to have turned up at the right moment, and he was thus enabled to obtain the funds necessary for passing an M.D. degree. He then for a time pursued a roving sort of life, not aimlessly, but with a fixed determination of being of some use in the world. Then came the war between England, France and Turkey, on the one hand, and Russia on the other. The general history of the struggle is well known, though various interesting episodes crop up from time to time in the course of his narrative of that campaign. The excitement of the war appears to have surfeited the writer, who subsequently settled down to peaceful pursuits, and of these the pleasures of travel, with the wide and varied information to be gained thereby, succeeded in engrossing his chief attention. His experiences and the incidents encountered in the course of his peregrinations and voyages are told in a familiar and unassuming fashion, and altogether the book, in which there are many illustrations, is one which may be recommended as a welcome companion during a leisure hour.

Kelly's Handbook to the Titled, Landed and Official Classes for 1893 London. Kelly and Co.—As stated in the preface, the object of this work is to include in one general alphabetical list all persons who have any definite position arising from hereditary rank, any recognised title or order, who are members of Parliament, or have distinguished status in the professions of law, physic and divinity &c. The Handbook is distinct in its scope and purpose, and does not intrude on the region occupied by directories of a somewhat similar character, but is useful as affording information which cannot be readily gained elsewhere.

The School Calendar and Handbook of Examinations, Scholarships and Exhibitions for 1893 London. Whittaker and Co.—In view of the possible passing in the near future of the Secondary Education (England) Bill that obtained last year a first reading, the book now under notice, which has reached its seventh year of issue, is likely to acquire increased usefulness. The information contained in it in respect of the nature and times of examination in universities, colleges and professional examining bodies during the current year is full and precise, and, so far as we have been able to observe, trustworthy.

exertion are far and away more healthy than others demanding little or no bodily effort. And all this is in harmony with what physiology proves—that the exercise of organs, and especially of the muscular system, is a pre requisite to health and preservative of life.”

As a necessary corollary to the above, Dr Arlidge gives it as his opinion that if there is to be any interference with the hours of labour it is not the more laborious and more healthful employments which should be first considered, but rather those industries which necessitate unwholesome work indoors, and which really deprive the artisan of what our author rightly styles the pre requisite of health.

The fourth chapter of this book is devoted to a classification of employments, non traders, traders, artisans &c., with their subdivisions, and the reader who wishes for information as to the diseases which are especially prevalent in any class of the community will here be provided with a storehouse of facts which have been collected with equal industry and judgment. Chapter five deals with the Pathology of Dust Inhalation, and the various employments which necessitate the inhalation of dust or noxious vapours are here passed in review. The amount of information contained in these last two sections of the work is very great indeed, and there is scarcely an industry, certainly no industry of any importance, of which the chief facts connected with its processes, and especially the injurious parts of such processes, are not given. These portions of the work do not lend themselves to quotation in a review, and it only remains for us to say that, having gone carefully through the book, we can confidently recommend it as a valuable work of reference to all who are interested in the welfare of the industrial classes.

Contributions to the Physiology and Pathology of the Mammalian Heart. Philosophical Transactions of the Royal Society. By Dr C S ROY and Dr J G ADAMI. 1892.

A PAPER occupying 100 pages of the current volume of the Philosophical Transactions by Drs Roy and Adami, entitled “Contributions to the Physiology and Pathology of the Mammalian Heart,” gives a careful description of methods, instruments and results, the outcome of ten years’ study, and will be welcomed by everyone interested in the mechanics of cardiac contraction. By means of the cardiometer—an instrument on the principle of the volume recorders or oncographs so successfully employed on the spleen and kidney—the authors took prolonged observations of the systolic discharge from the two ventricles and by means of an “automatic counter” they recorded the rate of total output. A third instrument—the myograph—served to record the changes of length of any desired portion of the ventricles, thus sampling the changes of their total circumference. These bare indications must suffice to indicate the means of approach devised by the authors, it is not possible to describe them intelligibly without figures. One of the most important results established is that normally the ventricles do not become completely empty at the end of systole, and we are told that with “increase of aortic pressure there is, other things being equal, an increase in the amount of residual blood.” The actual quantity of this residual blood, under various circumstances, as compared with the quantity expelled, in systole—data which must have been frequently under observation—cannot, however, be found, nor are any of the cardiometric tracings supplied with a scale so as to enable us to form more than an approximate estimate of the volume value of the lever excursions. Judging from the tracings, the systolic discharge (in small and medium sized dogs) appears to have been between 5 and 10 cc.—i.e., lower than the values observed by Stolnikow. A large number of the authors’ experiments relate to vagus effects—e.g., they show that with slower beat there is increased volume ($\times 2$, $\times 3$ or more), yet a diminution of total output (30 to 35 per cent.) From other experiments (chiefly by the myo cardiographic method)

we learn that the auricle is under closer subjection to vagus control than is the ventricle by reflex, as well as by direct excitation of the nerve, whereas the auricles (p 220) may be arrested for hours, the ventricles soon resume contractions with an independent rhythm—indeed, we are informed that the vagus neither weakens the ventricular contraction nor exerts upon it any antitonic effect (pp. 224, 227). Moreover, muscarin arrests the auricle, whilst the ventricle goes on independently. The augmentor effects occasionally to be observed by vagus excitation came under the authors’ observation, but are not believed by them to be due “to the presence of augmentor fibres such as are contained in the vagus of the frog,” and the supposition is made that they may act by producing dilation of the coronary arteries. They are met with only in ill conditioned animals. Evidence is also offered of the existence of cardiac fibres from the stellate ganglion, causing weakening of the auricular and ventricular contractions (p 247). These may “possibly” be constrictors of the coronary arteries, and the authors themselves lay particular stress upon this word “possibly,” having no evidence to offer in support of the supposition. Another section is devoted to the study of the augmentor nerves, and in conclusion the authors discuss the significance of the cardiac nerve mechanism from the teleological standpoint.

The Microscope its Construction and Management. By Dr HENRI VAN HEURCK, Professor of Botany at Antwerp. English Edition, re edited and augmented from the Fourth French Edition. Translated by WYNNE E. BAXTER, F.R.M.S. With Three Plates and upwards of 250 Illustrations. London: Crosby Lockwood and Son. 1893.

THIS very handsomely got up volume is much more than a mere illustrated catalogue of microscopes and microscopic apparatus, for it is written by an author who has himself made considerable improvements in the construction of various accessory pieces, such as the “comparing ocular,” and the “achromatic transformer,” and in the application of electricity as an illuminant. As Mr Baxter remarks, this work must necessarily be of interest to all who devote serious attention to microscopic work as a means of comparing the continental views and modes of thought with those of their own and other countries. The first chapter is introductory in its character, and deals with reflection and refraction of light, spherical and chromatic aberration and the general construction of the simple and compound microscope, the second chapter gives Professor Abbe’s theory of microscopical vision, and is followed by a paper written by Mr J W Stephenson, giving a series of experiments in support of Professor Abbe’s theory, both of which are interesting. The invention of the microscope is ascribed to Zacharias Janssen of Middelburg, about the year 1590, and the author describes briefly the several parts of an ordinary compound microscope. He then discusses the “objective,” and holds that the best test of definition is still the nineteen band test plate of Nobert, though it may be replaced by the graduated diatom test of Möller and the median nodule of the pleurosigma, which presents a small ball terminated by an excessively delicate thread which is lost in the raphé. This latter is stated to be a hitherto unknown and excellent method, well adapted for a photographic test. The “ocular” is then described, with its varieties, including Huygens’ and Ramsden’s orthoscopic, compensating and projection oculars. An immense number of excellent engravings show the construction of the stage and stand of the great microscope makers, such as those of Zeiss, Leitz, Ross, Powell and Lealand, Beck, Bénéche, Reichert, Bézu and Hauser, Hartnack, Chevalier, Nachet, Crouch, Watson and others. Many of these instruments are designed for special purposes. Those who are interested in photomicrography will find a chapter devoted to that subject. The author considers that if sunlight be used a heliostat must be

employed, and that the simplest, most practical and least expensive heliostat with which he is acquainted is that of Prazmowski, which is supplied in Paris by Bézu, Hauser and Co and in Potsdam by Hartnack. The last section of the work gives general rules for preparing microscopical objects, followed by a short history of the microscope and by a bibliography. The work reflects credit alike on the author, the translator and the publishers.

LIBRARY TABLE

Traité Élémentaire de Physiologie Par J V LABORDE, Directeur des Travaux Pratiques de Physiologie à la Faculté de Paris 1ere Partie. Pp 387 avec 155 figures Paris Société d Editions Scientifiques 1892.—M. Laborde's treatise commences with a brief but interesting chapter on the technique of operations on the frog, guinea pig, rabbit and dog, describing and illustrating the dissections requisite for the exposure of the heart, sciatic nerve and artery, external saphenous and jugular veins, the carotid artery and vagus in these animals. This section of the work stands therefore in relation to physiology as a dissector does to anatomy, giving an experimental demonstration of the facts stated—such, for example, as the action of curare, the proofs of recurrent sensibility in the motor roots the phenomena of the degeneration after section of the spinal nerves—instead merely of the dry facts. M Laborde does not think that the evidence at present advanced in regard to the capability of the conduction of impulses in either direction by every nerve fibre is valid. The evidence rests on Vulpian's experiment of dividing the lingual branch of the fifth and the hypoglossal nerves where they are in juxtaposition and effecting a suture of the central end of the fifth with the peripheral end of the hypoglossal. It is found that after the lapse of some months stimulation of the lingual above the point of union causes contraction of the muscles supplied by the hypoglossal. The defect of this experiment, as Vulpian himself pointed out, is that the chorda tympani, the fibres of which run in the lingual, is a motor nerve, and if this be cut no motor effects are observed. The second piece of evidence is that adduced by Paul Bert to the effect that the extremity of the skinned tail of a rat implanted in a wound in the back and divided at the root becomes attached, and after some months recovers its sensibility, but the objection here is that it is quite possible for union to have taken place between the sensory fibres of the tail and those of the skin of the back. M. Laborde thinks the only prospect of settling the question is by effecting union between the anterior and posterior roots of the second spinal nerve of the cat, in which animal the ganglion of this nerve is situated outside the spinal canal. He states that he is himself pursuing this inquiry. Continuing this subject, he gives the results of division of the several columns, of the grey matter of the spinal cord, and the laws of reflex action. He considers that the latter can best be shown in mammals by experimenting on kittens. If in these animals the calvaria be removed and the cerebrum be cleared away by a stream of hot water till only the pons Varoli is left the animal will remain alive for nearly a day, and all reflex actions can be well demonstrated upon it. After a careful exposition of the various theories that have been advanced—some on the basis of experiment some on anatomical grounds and others again, on pathological ones—in regard to the use and functions of the cerebellum, M Laborde believes that the most correct view is that it is an organic centre of coördination and regulation of voluntary movements. Its normal activity is essential to the preservation of the harmony and the equilibrium of the movements and to enable them to work efficiently and surely together. The wide subject of the cerebrum and its functions is well and fully given. Altogether the work fairly

represents the present standpoint of modern physiology, though we should like to have seen some notice of recent English work, such as that of Dr Gaskell and Dr Sherrington.

Royal Road to the British Pharmacopœia By WALTER F CLAYTON London Harmer and Harley 1892.—In the introductory remarks the author commends his mnemonics to pharmaceutical, medical and other students, and he wishes his rhymes to be so thoroughly committed to memory that they may be recalled "and repeated mechanically," "without effort or apparent application of thought." He does not indicate to whom they are to be "repeated mechanically," nor what result might be expected to follow such lack of "application of thought." The doggerel verses are very much of the usual type, abbreviations abound, and t scanning is not always an easy matter. No doubt, if studied first in conjunction with the Pharmacopœia, these mnemonics might be useful to some students, but they leave many important official preparations untouched and appear to lay stress upon many which no one could possibly be expected to commit to memory.

Seventy Years of Life in the Victorian Era By A PHYSICIAN London Fisher Unwin. 1893.—This is a pleasant, gossiping narrative of the experiences of one who has seen a good deal of the world ashore and afloat. Its descriptions of foreign parts are interesting and, without any attempt at literary display, the author has managed to import into his diary (for the record assumes this form for the most part) a considerable amount of information, useful as well as attractive. Pecuniary difficulties hampered the early career of the author, but friends seem to have turned up at the right moment, and he was thus enabled to obtain the funds necessary for passing an M D degree. He then for a time pursued a roving sort of life, not aimlessly, but with a fixed determination of being of some use in the world. Then came the war between England, France and Turkey, on the one hand, and Russia on the other. The general history of the struggle is well known though various interesting episodes crop up from time to time in the course of his narrative of that campaign. The excitement of the war appears to have surfeited the writer, who subsequently settled down to peaceful pursuits, and of these the pleasures of travel, with the wide and varied information to be gained thereby, succeeded in engrossing his chief attention. His experiences and the incidents encountered in the course of his peregrinations and voyages are told in a familiar and unassuming fashion, and altogether the book, in which there are many illustrations, is one which may be recommended as a welcome companion during a leisure hour.

Kelly's Handbook to the Titled, Landed and Official Classes for 1893 London Kelly and Co.—As stated in the preface, the object of this work is to include in one general alphabetical list all persons who have any definite position arising from hereditary rank, any recognised title or order, who are members of Parliament, or have distinguished status in the professions of law, physic and divinity &c. The Handbook is distinct in its scope and purpose, and does not intrude on the region occupied by directories of a somewhat similar character, but is useful as affording information which cannot be readily gained elsewhere.

The School Calendar and Handbook of Examinations, Scholarships and Exhibitions for 1893 London Whittaker and Co.—In view of the possible passing in the near future of the Secondary Education (England) Bill that obtained last year a first reading, the book now under notice, which has reached its seventh year of issue, is likely to acquire increased usefulness. The information contained in it in respect of the nature and times of examination in universities, colleges and professional examining bodies during the current year is full and precise, and, so far as we have been able to observe, trustworthy.

THE LANCET.

LONDON SATURDAY, MARCH 11, 1893

THE friendly action which was instituted between the Royal College of Physicians of London and the General Medical Council to determine the legality of the claim of the former to the registration of its licence as a complete qualification in medicine, surgery and midwifery has at length been tried and has resulted in judgment being given in favour of the College. This is what we anticipated would be the issue. When writing after the first step in this contentious business had been taken we pointed out that the College had "since 1858 exercised its power of granting a complete qualification, and that that power was not removed by the Act of 1886" (THE LANCET, Dec 5th, 1891, p 1287). The legal proceedings, which culminated on Wednesday last in the judgment given by Lord Justice A. L. SMITH, arose out of the resolution passed by the Medical Council on Dec 27th, 1891, by a majority of 19 to 6. That resolution, moved by Sir W. TURNER and seconded by Sir JOHN SIMON, ran as follows—

"That as the claim made by the Royal College of Physicians of London that its single diploma of Licentiate or Member should admit to the Medical Register without any additional qualification would involve the admission by the Council that the College can itself confer a complete qualification in medicine, surgery and midwifery, and as this claim is based upon the interpretation of the Charter of the College along with the Medical Acts of 1858, 1860 and 1886 the Council leave it to the Royal College of Physicians to substantiate their claim in such a way as they may think fit and in the meantime instruct the Registrar not to register the qualifications of Licentiate or Member of the Royal College of Physicians of London as in themselves sufficient to admit to the Register."

The issue before the Court was, as Lord Justice SMITH said, a narrow one. It was whether at the time of the passing of the Medical Act (1886) the College of Physicians was a corporation legally qualified to grant diplomas in respect of medicine and surgery. This he held to have been clearly established. To determine this the judgment went back to the original Charter of Incorporation granted to the College by HENRY VIII, and he especially directed attention to the Act of 1540 which in its second section expressly includes within the definition of "physic" the "knowledge of surgery as a special member and part of the same." At the same time it is true that, as Sir HORACE DAVEY said, the Charters granted to the Society of Barber Surgeons, with which eventually the present Royal College of Surgeons was incorporated, did imply a distinction between the practice of surgery and that of physick. It is clear, however, that the College of Physicians possessed the right to give qualifications in surgery as well as in medicine, although it was not until 1862 that it imposed an effective examination in the former subject.

The College of Physicians has always maintained that in consenting to conjoin with the College of Surgeons for the purpose of granting efficient diplomas it had reserved its primary and peculiar privilege of granting diplomas which by themselves should entitle the holder to registration under

the Act of 1886. It was this claim that the General Medical Council disputed, and it may be recalled that on the occasion of Sir W. TURNER's motion, which has been the cause of this litigation, some members of the Council did not hesitate to impugn the sufficiency of the examinations conducted under the authority of the College. The attacks upon the College examinations were based on a confusion between the two very distinct classes of test applied to the Licentiates and the Members of the College respectively, for the latter is admittedly confined to the subject of medicine, and had it not been for the erroneous registration of a Member by virtue of this single diploma alone all the subsequent dispute might have been saved. The General Medical Council have not only failed to prove their point, they have elicited a judgment which, so far as the strict legal interpretation of the powers and privileges of the College goes, may be construed to award the College even more than it asked for, for it may be observed that the learned judge in his remarks made no distinction between the Licentiates and Fellows. He held that the term "physic" comprised that of surgery, and the logical inference is that instead of limiting the admission to the Register to those who have been actually examined in medicine, surgery and midwifery the General Medical Council might be compelled to admit Members and Fellows who possibly may not hold any diploma in surgery at all. We do not suppose that the College would ever press its rights in that direction. It is enough for it to have obtained confirmation by a court of law of its contention that the diploma granted for its licence is a qualification in medicine, surgery and midwifery, and the College may be trusted to maintain the standard of the examinations for that licence at as high a level as those for the Conjoint Board. We have not much sympathy with the General Medical Council, whose action implied that the College of Physicians, by retaining its ancient privilege, was unworthily endeavouring to open a back door to the Register, and we also think that if the facts had been impartially and fairly reviewed on the original occasion the majority of the members of the Council would never have taken a step which has led to this legal rebuff. On the other hand, the Licentiates of the College will be relieved to find that they have as much right to registration as any other holders of diplomas in the subjects of medicine, surgery and midwifery. The terms of conjunction with the College of Surgeons are such as to reduce in the future the possible number of holders of the licence alone into a very small proportion indeed, but it must be consoling to the College of Physicians to feel that, come what may, it can grant registrable diplomas without appealing to the General Medical Council for assistance in the choice of examiners.

APART from the interest of the recent speech of Lord SALISBURY at Oxford as a local question or its bearing on academic duties, it has a high interest to members of the medical profession. It is, indeed, a fact for medical men to note that the present and the late Premiers of England—her two foremost and most conspicuous statesmen in the last decade of the nineteenth century—have each taken occasion to speak in terms of high eulogy of the great profession of medicine and of its prospects. Some superficial observers talk as if medicine will be superseded as civilisation

advances That is not the opinion of either Mr GLADSTONE or Lord SALISBURY Mr GLADSTONE, observing, we fear, the increase in the remuneration of medical labour, told us last week that certainly no fees were more nobly earned than those of medical men. Two years ago, in his capacity as Senator Governor of Guy's Hospital and when opening there a new medical college, he told us that ever since the time of MEAD and FREIND the profession had been steadily rising into a position of influence and power and general recognition, and that in his opinion it would continue to rise with the growth of civilisation which involved wants and infirmities which are the opportunity of medical men. Civilised man is more sensitive to pain than his savage brother, and we fear we must admit that the growth of civilisation neither abates his sensitiveness nor increases his tolerance of suffering. Worrr is very much a product of civilisation—one of those refined and indefinable influences scarcely felt by savage races, tending to undermine health and predispose to disease. The factor of worrr in the production of disease is very marked, and if medicine has not yet discovered a specific it is constantly in demand for means for the reduction of the effects of this morbid influence, and it may be assumed without undue boasting that the wise physician ministers to the sufferers from worrr as powerfully as any other philosopher or friend. How much more brilliant is the service of medicine in the mitigation or removal of actual pain, even when amounting to agony by the discovery and application of substances which control it and often the conditions and the causes of it. The eulogy on medicine as a science delivered by Lord SALISBURY at Oxford in his capacity of Chancellor of that ancient University is, indeed, one of the most significant and complimentary deliverances on the subject which history has to record. To be candid, it is one which could not have been pronounced with perfect accuracy until a period not far removed from the present. No doubt the true exponents of medicine have for a long time been on the track of truths of the highest moment to the human race, but it is chiefly within the last thirty years that a great advance has been made in the methods of medical investigation, the faithful pursuit of which promises the highest results for the welfare of nations and of individual men. Lord SALISBURY deserves credit for his courage in rising at Oxford, of all places in the world, the ground of the claim of an infirmity from one of mere charity—though that is high ground indeed—to that of his power to minister to the cultivation of one of the greatest of the sciences—the science of medicine. There have long been at Oxford men like Sir HENRY ACLAND and Dr BUCHAN SANDERSON who perceived the true greatness of medicine and wherein it consisted, but it is useless to deny that they have been 'sore let and hindered' in trying to give it academic encouragement and position. The problems of life, as viewed by the physiologist and the physician—a view that is now being increasingly forced on all thoughtful men—have not been the problems that have hitherto commended themselves to the study of the men who have guided Oxford. Now that the two most powerful of her sons have so emphatically declared the importance of medicine not only as a profession but as a science (in Lord SALISBURY'S studied words 'the most sober, the most absolute, the most positive of all sciences') we may confidently hope to see

Oxford begin seriously to make amends for her neglect of this science in the past. For the understanding of man in all his relations and interests this science is indispensable. Truly, as Lord SALISBURY says it is occupied largely just now in the attempt to investigate the "infinitely little", but there is high authority for saying that the "small things" of the world have been made to confound the things which are mighty and more than once the heart and history of England have been mightily affected by the action of these said 'small things' on her people and her potentates. The methods of medicine are now of the severest scientific kind, and would have been so long since and much sooner if such bodies as the University of Oxford had done their duty by science. She can make amends now just as her sister University of Cambridge has done. We admit that it was easier for Cambridge to graft on her mathematical school a great medical school as she has done but still as Lord SALISBURY says Oxford has abundant means of teaching the group of sciences which are the equipment of the physician if she will but give her mind to the claims of science. If Oxford does not make amends she will be the loser. Unless both Mr GLADSTONE and Lord SALISBURY are wrong in their estimate, medicine is building on sure foundations a high and a lasting place in the estimation of mankind, and, unless her devotees stray into other paths than those in which they are at present reaping such precious fruits, their claim to a higher recognition than any at present accorded to them both by the State and by the educational bodies of the country will become irresistible.

We will, in conclusion, notice only one fact of interest in connexion with these remarkable pronouncements of the Premier and the ex-Premier. Both of them have been made, not when the speakers were in power, but when they were in opposition. We do not mean by this to imply that we have any doubt as to the sincerity of the speakers in expressing such opinions. It is the advantage of the relegation of such minds to the comparative leisure of opposition that they have time to consider other branches of knowledge than those immediately concerned in legislation and administration. Is it, however, too much to expect that when in power they will use their influence to secure for medical men that place and that recognition in the State which is surely the due of those who represent 'the most sober the most absolute and the most positive of all sciences' which is also in its office 'only another name for a work of mercy more closely linked than any other with the relief of human suffering and the remedy of human calamity in its worst and most overwhelming forms'?

SCOTLAND is fortunate in having at the fountain head of its active asylum life and work a man so able as Dr CLOUSTON and the *Scotsman* of the 23rd ult. in referring to his last annual report as Physician Superintendent of the Edinburgh Royal Asylum for the Insane, is fully warranted in speaking of him as 'one who besides possessing the knowledge and authority of a specialist in mental diseases has a wide practical acquaintance with, and a deep philosophical interest in the great social questions of the day. Without being afflicted with the clerical scruples Dr CLOUSTON is never unwilling to express

his views upon paper, he is not a faddist and his writings are always readable and interesting and full of common sense—characteristics which give his annual report a value that seldom attaches to the almost always dull sentences of the average Blue book. Dealing with the ever recurring question of the increase of insanity, Dr CLOUSTON tells us that in Scotland generally there is now one rate paid insane person to every 392 of the population, while ten years ago the proportion was one to 435, showing an increase of insane to sane of 11 per cent. In England the rate paid insane is found to be one to every 335 of the population now as against one to every 347 ten years ago. Scotland therefore has the advantage of England in total numbers, but the proportion of increase in the insane in England has only been 3.3 per cent. in the ten years against Scotland's 11 per cent. Some explanation of this is sought in the fact that a Lunacy Act has been longer in operation in England than in Scotland by a period of twelve years, thereby facilitating the official recognition of the insane, but we cannot help thinking that this explanation ought before this to have arrived practically at vanishing point, seeing that the English Lunacy Act has been in existence for half a century. Other causes of the difference must be sought for, and they will no doubt be found in groups of circumstances and social conditions which are found to vary in their outward expression amongst the populations of the two countries, where we have, besides legislation and classification, methods of distribution as to the insane established on lines that are by no means parallel.

That this contention has some weight is evidenced by statements made by Dr CLOUSTON himself. For instance, with regard to Ireland, where the Lunacy Act has been in operation longer than in Scotland, he points out that there is now the very large proportion of one lunatic to every 280 of the population, while ten years ago that country had only one to every 371, showing an increase now of 32.5 per cent. Again, in this relation, he refers to an individual Scottish county, Argyle, where there was one insane person to every 200 of the population, but the increase of that proportion in the last ten years has only been half of what it had been in Ireland. Dr CLOUSTON thinks that the natural explanation in both cases is a "diminishing population through the emigration of many of the most energetic and healthy, the poor and the old and the lazy, the insane and those lacking in intellectual and physical energy, being left." No one will be disposed to question this broad statement, which exemplifies one of the conditions in active operation as a means of disturbance in the balance of the proportion of the insane to the sane in one country as compared with another. Leaving the pauper lunatic, Dr CLOUSTON becomes critical on the subject of the non-pauper insane. He points out that in Scotland the number of the self-supporting insane now stands in almost the same ratio to the population that it did in 1876, and this in spite of an enormous increase which Dr CLOUSTON says has taken place in the proportion of well-off people in the country. "If," he says, "insanity should its increase be confined to those who got treated at a public expense?" a pertinent question, if it is so confined.

On this subject we should have been glad if Dr CLOUSTON had given us some supporting gleams of comfort from a comparison with statistics in England. In its greater comparative homogeneity of race, and presumably of hereditary mental constitution, Scotland affords, as compared with England, a sufficiently circumscribed sphere for the study of national characteristics, whether normal, abnormal, or diseased, and it is most interesting to find Dr CLOUSTON raising valid and strong questions of the sort, even although only in the limited compass of an annual report. The *Scotsman*, in its leading article, says on this subject: "It has been contended, and there is a good deal of evidence as well as probability to support the contention, that this spread of mental infirmity is part of the penalty which the human organism and intellect have to pay to modern civilisation—that the brain is harder worked and suffers more frequent breakdown, that the pace is telling on the race. The gains may be worth this and other items of cost, but humanity would certainly be put somewhat out of concert with progress on present lines if it could be shown that the higher the plane of civilisation the greater the proneness to madness." Are Dr CLOUSTON's figures and statement of opinion on this subject accurate and incontrovertible as regards Scotland? And if as regards Scotland, are we to interpret them as being applicable to England and other countries? We hesitate to accept the minor proposition without more complete demonstration. As we have pointed out above, Dr CLOUSTON shows that, through emigration of the most energetic and healthy, those lacking in intellectual and physical energy are left. The traditional allusion to Scotsmen leaving home in search of the fleshpots of the South has in this relation a significance and a force not usually claimed for it, and that it applies not merely to individuals of the labouring and less intellectual class is evidenced by the eminent success of Scotland's sons in all parts of that empire upon which the "sun never sets." We merely suggest this general point as a factor for consideration in an important question of this kind. And, again, even if the most highly civilised individual himself has been blessed with stability enough to avoid relegation to the ranks of the insane, may he not be responsible for the initiation, or at all events for the transmission to his offspring, of a possible heritage of nervous instability or proneness to insanity which renders them less able to earn their livelihood and to resist becoming rate paid inmates of asylums? Our readers will do well to obtain this report on the Edinburgh Asylum for 1892 and study it for themselves.

So far as may be gathered from the columns of the local press the authorities of Leicester have been acting very much at cross purposes since small pox arose in their town, much to the surprise of certain of its councillors, who have for years past not only been vaunting the superiority of Leicester and its "method" of dealing with that disease, but have also been sedulously decrying the efficacy of vaccination. The *Leicester Daily Post* of March 1st gives a strange insight into the doings of this much perplexed and much divided municipality, which has not the courage of its opinions, but is content to waste time and money over an "inquiry" into the causes of the outbreak, whilst refusing grants to improve the accommodation.

tion so sadly needed for the isolation of infected families. We cannot think that the proceedings of the Town Council during the past few months will be regarded with satisfaction when its history comes to be written. It seems to be occupied largely in checking the endeavours of the sanitary committee to cope with the disease out of consideration for the ratepayer, whilst it has sanctioned a wilful expenditure on an inquiry which can lead to no good end. To review the whole of its proceedings during this period would entail more space than they merit, but they may be summed up in a word as a policy of drifting, which began last autumn when the proposal to erect a new fever hospital, although it had been adopted and the plans had been approved, was abandoned. Then small pox broke out, and the effete buildings, which had been put up twenty years ago and which were at the time largely occupied by scarlet fever cases, had to be utilised for the reception of small pox cases. Of course, some of the unfortunate children in the fever wards contracted small pox, it is only surprising that more of them did not take the disease than were attacked, so close is the proximity of the fever wards to the small-pox wards. Still, there was a sublime confidence that Leicester was not likely to suffer from an epidemic of small pox, the "Leicester system" being all sufficient, and it would almost seem as if the inquiry which the sanitary committee have instituted were the result of chagrin at the failure of the "system" to keep out the disease, for in spite of confident predictions to the contrary, Leicester has not been free from small pox since September last. As to the steps taken by the sanitary committee and the Town Council, we cannot do better than quote from the leading article in the above named journal which commented on the proceedings of the meeting of the Council held on Feb 23th—

"Our guardians of the public health formally recommended that the Council should accept a tender of £1762 for the erection of a building adjoining the fever hospital, as previously authorised by the Council. Not only, however, was this proposal negatived, but it was superseded by a resolution that the Council should apply to the Local Government Board for power to borrow £2500 to carry out some similar scheme or other which was not specifically identified. Of course, the open secret of this latest change of front—this new reverse for the unfortunate and bewildered sanitary committee—is only too plain. It is to be found in the impending Budget with its huge addition to the rates and the irresistible fear that the imposition of another penny in the pound would provoke an absolute revolt on the part of the already alarmed and indignant ratepayers."

The article goes on to admit the "utter inadequacy of the present hospital alike in accommodation and internal arrangements" and the need for another building for the purposes of isolation and quarantine, but, as if to show how hopelessly at variance with one another the very members of the committee are who are entrusted with the system associated with Leicester we find the following frank admissions in a later paragraph—

The striking feature of the debate was its testimony to the necessity of reconsidering at least one part of the municipal plan of campaign against small pox. We allude to the "ro ten and expensive system"—to quote the scathing indictment of the vice chairman—by which large numbers are housed at the hospital, fed like fighting cocks on beef and beer, and yet not sufficiently isolated to be as thoroughly quarantined as they might and otherwise would be at home. Certainly if this specific feature of the Leicester experiment

has proved a comparative failure—and it is frankly admitted—its supersession by the economical and more efficient home system can hardly be too rapid and complete."

And these are the words of a writer who cannot, we imagine, be actuated by any desire to humiliate Leicester or to depreciate its capability for dealing with infectious diseases. In one passage there are pleas for extended provision for "quarantine" and in another a desire to abandon the "system" altogether. The fact seems to be that this visitation of small pox, which found Leicester lulled into a false security, has revealed a lamentable state of indecision and unpreparedness amongst those responsible for the health of the borough. The outbreak is not yet over, it may at any time attain dimensions which will necessitate very vigorous action, but no impartial onlooker can come to any other conclusion than that Leicester has forfeited its claim to be considered as a municipality which is possessed of ordinary foresight in dealing with zymotic disease. However, as if in vindication of its apathy in one direction, we read in the *Leicester Daily Post* of Feb 28th that on Feb 27th a man was prosecuted for failing to notify a case of small pox in one of his children, who appears to have been attacked subsequently to the cessation of the surveillance to which his household had been subjected on the illness of another child. The case was held to be proved and a fine was inflicted, the penalty being mitigated in consideration of the fact that two or three more of his children have been attacked with the disease, of whom one has since died. The defence was a plea of ignorance of the nature of the illness—a perfectly reasonable ground, but under the special circumstances of the case this plea could hardly be sustained. No medical man was called in to this case, and the parents may have hoped against, or have shut their eyes to the possibility of its being small pox. The previous case had been treated at the hospital and they must now bitterly regret that they did not take steps to prevent the infection of their remaining children by notifying the medical officer of this case or, at any rate, of consulting him as to its nature. It is, however, not unlikely that they, as so many of this class do, did not believe in the contagiousness of small pox, which has had for them such disastrous results. We should be sorry to think that they had ever been encouraged in that opinion, although there is no accounting for the vagaries of some would-be instructors of the people on these subjects.

Annotations.

"No quid nimis."

ALABASTER AND OTHERS v THE MEDICAL BATTERY COMPANY

THIS case, which was tried on Tuesday and Wednesday last in the Queen's Bench Division before the Lord Chief Justice and a special jury formed a fitting sequel to the case of Tibbits v Alabaster and Others which was reported in THE LANCET of Feb 25th. It will be within the recollection of our readers that the former action was brought by Dr Tibbits, who had been severely criticised in an article in the *Electrician* for the part which he had taken in support of the trade in "electrostatic belts." Dr Tibbits, however, failed signally to make out his complaint, and although he had been subjected to a very severe attack the

jury awarded their verdict to the defendants. The Medical Battery Company seems, however, to have thought that it would be a good thing to retaliate upon its critics by attacking the circulation of their paper, and accordingly caused a circular letter to be addressed to the news-vendors of London denouncing the criticisms in the *Electrical Review* as "malicious libels," and warning the tradesmen that they would be held personally responsible if they continued to circulate defamatory statements concerning the Medical Battery Company. The strategy of this measure was exceedingly well conceived, and for a time very serious inconvenience, and even injury, was inflicted upon the proprietors of the newspaper. Their customers, being very naturally indisposed to interfere in the discussion, demanded an indemnity and refused otherwise to circulate the paper. The indemnity, therefore, had to be given and a responsibility assumed which might well have deterred less resolute journalists from maintaining so arduous a struggle. The proprietors of the *Electrical Review*, however, did not tamely submit to this inconvenience. On the contrary, they brought an action for the libel contained in the circular, and claimed damages in respect of the injury done to their trade. They have succeeded in the most ample measure, and it is matter of satisfaction, not to them selves alone, that their verdict of £1000 will probably make the directors of the Medical Battery Company and other persons like minded hesitate before renewing the attempt to stifle criticism in this way. The damages are significantly heavy, but, having regard to the conduct of the defendants both before and at the trial, we are bound to say that they do not appear to us to be excessive. They signify of course, that the jury felt that the case was one for exemplary treatment. The defendants had been denounced as persons who traded upon the weakness and credulity of sick and suffering people, and who sold worthless trash under the name of curative appliances. When evidence in justification of these most serious charges was tendered they endeavoured to shut it out upon a technical objection, and when their objection was overruled they did shut it out by admitting the libellous character of the circular and going to the jury on the question of damages alone. That the jury should have thought that such chicanery deserved to be visited with heavy damages does not surprise us, and although we think that there is, perhaps, at the present time some disposition on the part of juries to exaggerate the offence of libel and to award, when it is proved, disproportionate damages, we consider that there never was a case in which severity was more merited by the circumstances of the offence or better calculated to prevent its repetition than the present, an account of which will be found in another column.

YEW POISONING

To determine the causes of the capricious occurrence of yew poisoning in cattle Mr Stuart Wortley undertook some experiments and published his results in *The Times* in the course of last summer. His letter was followed by a conflict of evidence from various quarters, the general bearing however, showing a widespread belief amongst agriculturists in the frequent toxic influence of the yew. Little good could be expected to result from the discussion of such a question in a daily paper, hence it is satisfactory to find that the matter has been revived in a quarter which is more likely to yield material based upon accurate observation and research. The journal of the Royal Agricultural Society contains papers by four writers, each of whom discuss the subject from a different point of view. Mr E P purpose gives from his own experience a list of the most its primary instances of deaths of animals after eating the yew trees. His examples include the Irish yew, by themselves. Court yew (*taxus fastigiata*), and the English

yew (*taxus baccata*), and they show also that the nature of the soil upon which the plant grows appears to have no influence in promoting toxic effects. Mr Charles Whitehead, after noting the small amount of definite information in English works, gives a summary of a recent French publication by M C Cornevin, professor at the National Veterinary School. This writer is of opinion that yew does not act as an irritant, but as an anæsthetic and narcotic at first and later on by stopping the action of the heart and by affecting the respiratory system. Judging by analogy, he thinks it acts upon the nerve centres. In view of the rapidity of action, M Cornevin makes the very ingenious suggestion that there may be a chemical combination within the animal organism analogous, perhaps, to that which produces prussic acid in certain species of *amygdalus*. The third paper is from Mr William Carruthers, F.R.S. he gives a reference to a description of toxic symptoms in man, he states, as a matter of common knowledge, that children eat the fleshy part of the fruit with impunity, but that when the thin crust surrounding the seed is broken, and the seed itself crushed and swallowed, fatal results have ensued. On the other hand, he doubts whether there is any foundation in fact for the asserted differences in toxic qualities in the stem or foliage of the two sexes of the yew. In the fourth paper, by Mr J M H Munro, chemical questions are mainly dealt with. The methods of separating the specific alkaloid *taxine* are given in detail and it is suggested that chemical changes in it may have been produced in the processes of extraction employed by Amato and Caparelli. While admitting that *taxine* is probably the poison of the yew, it is considered doubtful whether it has ever been obtained in a pure state, and also probable that other alkaloids are present. In Mr Munro's experiments he obtained a greater quantity of crude alkaloid from the male leaves than from the female, but he does not regard this result as conclusive and he suspects that the successive stages of purification cause an actual alteration in composition. The whole question, therefore, of the precise conditions under which yew is poisonous to horses, cattle, sheep and "game" still remains unsolved, though its importance merits, and will doubtless receive, the closest investigation.

THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

A MEETING of the Committee of the Association of Fellows of the Royal College of Surgeons of England was held on March 8th. Mr George Pollock, the President of the Association, occupied the chair, and there was a large attendance of members of the Committee. The minutes of the last meeting were read and confirmed. The hon secretary read several letters of regret from members of the Committee who were prevented from attending. He also reported that the correspondence between the Committee and the President of the College had been printed and sent to every Fellow of the College whose address was known, as well as to the medical journals, in accordance with the instructions given to him at the last meeting of the Committee. It was for the Committee to decide whether any further step should be taken in the matter. A discussion ensued, and the general feeling was that, as the Association had been sufficiently vindicated, it was undesirable to take any further action. The next subject of discussion was the vacancies on the Council of the College which will be created in July next by the retirement in rotation of three members of that body in accordance with the charters. It was reported that the retiring members would be Sir Wm Savory, Bart, Mr C N Macnamara and Mr Oliver Pemberton. The hon secretary was instructed to write to the two latter gentlemen, who had been connected with the Association for some years, and at a previous election had received

the support of the Association, for the purpose of ascertaining whether they intended or not to offer themselves for re-election, as the nature of their replies would largely determine the action of the Committee in regard to the nominations and support of candidates at the election next July

THE LANDSLIP AT SANDGATE

IN the calamitous landslip at Sandgate, due, it has been alleged, to the subsidence of the sandy hills on which the town is built on their being left dry by the return of the sub-oil at ebb tide, and accelerated, no doubt, by the exceedingly rainy weather which was prevalent during almost the whole of the month of February, the seaside convalescent home known as the "Beach Rocks" has fortunately escaped damage and is being requisitioned by the Admiralty and many others as a resort for those who have been rendered destitute and homeless by the aforesaid catastrophe. We are informed that on Sunday night much alarm existed amongst the inmates, but this was allayed by the combined efforts of the nursing staff and of the secretary, Mr John James Jones, who during the whole of the night was present in the home to render any assistance that might have been found to be necessary

THE LANCET INVESTIGATIONS ON CHOLERA IN FRANCE

Le Petit Marseillais of March 4th contains an interesting account from the pen of M. Gaspard Galy of an interview which he has had with our special correspondent, who is at present investigating the conditions and circumstances to which the recent outbreak of cholera in Marseilles may be attributed and the results which have arisen in consequence. In the course of the article the former observations and researches which have been from time to time published in the columns of *THE LANCET* and which our correspondent has, after much labour, been able to supply to our readers, are set forth with considerable detail. The writer says "La grande publication anglaise *THE LANCET* qui fait son objet spécial des questions de médecine, de chirurgie et d'hygiène vient d'envoyer son rédacteur spécial à Marseille, où il vient procéder sur place à une enquête sur les causes et les effets des dernières épidémies. He goes on to say that he has followed with much interest the plans and drawings which our correspondent had laid before him and which rendered it easy for him to understand the sanitary history of the town. He further states that our special correspondent had cited examples of the absolutely ridiculous means adopted in certain localities for combating the disease.

— AND COCOA

Imperance is a gain to national opinion in noticing such an advance achieved recently by Dr W Wood of the Worcestershire Health Society. The 'Tea and Cocoa.' As might have been expected of these beverages received the same consideration. Its varieties, its different chemical properties, its modes of preparation and erroneous were discussed at some length and with the happy result that it may still be regarded as a wholesome stimulant and restorative of the nervous system which if properly made and used in moderation, is guiltless of after ill effects. A comparison between the different known methods of preparing tea is of some general interest, the Japanese plan—which allows infusion for about a minute and a half, and which does not require boiling water, cream, or sugar—having evidently an attraction for the lecturer. For general use, however he recommends the ordinary British custom, the infusion being drunk whilst recent and

not strong. In this country we stand in equal, if not greater need of teaching in regard to the qualities and preparation of coffee and cocoa. The former of these wholesome luxuries was treated of in considerable detail. We should have welcomed a somewhat fuller exposition of the properties and uses of the latter. A recommendation of cocoa in the nourishment of infants is, however, noteworthy and should prove of some practical service. The question of cost was not forgotten. The estimate for a cup of good tea (3d) and of good coffee (4d) is instructive when the prices charged in many restaurants for infinitely poorer stuff are held in mind.

MEANS OF ISOLATION AT WEST HAM

WEST HAM is in considerable difficulties as to hospital accommodation for infectious diseases. The question of small pox has again and again been the cause of postponing the provision of a hospital and it still stops the way to some extent. There is a building that might be used were it not that if small pox were received into it a Poor law institution would suffer. Dr Barry, representing the Local Government Board, has conferred with the sanitary authorities within the West Ham Union and at a preliminary interview he advised the formation of a joint hospital board and the provision of separate hospitals—one for small pox and another for the other infectious diseases.

DEATH UNDER CHLOROFORM

A DEATH under chloroform took place at Hanley on Feb 21st. The patient was a well built and robust young man of thirty four, a mould maker, who had contraction of the palmar tendons of the right hand caused by an injury he had received some years ago. It was with the view of setting free those tendons that Mr W D Spanton had undertaken to operate. Chloroform was administered by Mr Aiken, the patient having been previously put to bed in his own house. The patient took the anæsthetic well. There was a good deal of shouting during the stage of excitement, which passed off as usual with a brief general spasm of the muscular system, and then the man's respiration became regular and he was pretty well under the influence of the anæsthetic. It was shortly after this, about ten minutes after the commencement of the administration of chloroform, that the pulse suddenly ceased, the respiration stopping immediately afterwards. The tongue was pulled out and artificial respiration performed, and a nitrite of amyl capsule was held under the nostril, but although artificial respiration was kept up for some time there was not the slightest sign of returning consciousness. The chloroform was administered on a fold of lint, held a little distance over the mouth, the operation had not been commenced. A post-mortem examination of the body was made by Dr Charlesworth and Mr Adler. The lungs were congested and the right side of the heart was full of dark liquid blood. The walls of the heart were flaccid and somewhat thin. The man had always enjoyed good health.

THE "ESPOSIZIONE OF THE INTERNATIONAL MEDICAL CONGRESS

AN Italian correspondent under date Rome, March 5th, writes. Among the many features in which the organising committee are working to make the coming Congress a distinct advance on its predecessors is that of a medical exhibition which shall place on view, conveniently arranged and effectively catalogued every article, object, appliance or appurtenance of the healing art in its widest acceptance. A special 'Comitato Esposizionario' has just been appointed *ad hoc* including such representative names as that of the Commendatore Professor Pagliani Director of Public Health, Signor Bentivegna, the distinguished engineer, Signor Marzan, a public auditor of approved

ability, and others not less fit for the work of organisation. Professor Pagliani is its president, and under his energetic auspices circulars inviting the contribution of specimens of every kind of medical *materiel* are now ready for transmission to pharmacutists, surgical instrument makers, food manufacturers, wine growers, mineral water agents—to all, in short, who cater for the professional requirements of the practitioner. Many of these specimen contributions, indeed, are on their way to the 'Esposizione,' their contributors being, not unnaturally, interested in securing an advantageous *locale* for their contributions. The alimentary and wine departments will, I have good reason to know, be richly represented not only by Italian purveyors and by British houses established in Italy, but by those of other nationalities—Swiss, Austrian and German in particular. For all contributors from abroad the Commendatore Pagliani is exerting his great influence—parliamentary, social and professional—to secure facilities for the convenient consignment of their wares *en route* to the Exposition by reducing railway charges and minimising Custom House formalities to the vanishing point. That the 'Esposizione' shall be 'la nota saliente' (the outstanding feature) of the Eleventh International Congress of Medicine and Surgery is the avowed object of the Commendatore Pagliani and his coadjutors on the committee, and certainly they are sparing no effort to be as good as their word."

EMPLOYMENT FOR THE BLIND

WE may safely say that, with the exception of those mentally afflicted, no class of the population have suffered so much from the want of employment entailed by their condition as the blind. They have not, indeed, been left altogether without means of livelihood, and some few, favoured by social position and means, have attained to the discharge of great and useful functions. As a rule, however, the blind man's calling has consisted merely in the practice of some simple handicraft requiring for its exercise only the most moderate amount of intelligence. Of late years a change has begun to come about. Much has been done by means of specially directed education to increase the intellectual and practical energy of this once neglected class and thus to justify their occupation in work of a more complicated and responsible character. There exists in consequence a need of such employment, so modified and adjusted that the sense of sight shall not be indispensable to its exercise, and indications are not wanting to show that the demand may be satisfied. As an illustration we may mention the recent introduction by Mr F W Smith of Brighton of a typewriter intended for the use of blind persons which prints embossed characters and is adapted to any type. This invention, we repeat, is noteworthy, not only for its own sake, but as indicating the growth of a purpose which promises to bring more and more within reach of the hitherto incapable blind a considerable part at least of the privilege of work enjoyed by their seeing neighbours. We might suggest the telephone and even the telegraph systems as other possible outlets for their energies.

ANNUAL DINNER OF THE ROYAL MEDICAL SOCIETY OF EDINBURGH

THE dinner of this Society was held in the Waterloo Rooms, Edinburgh, on the 3rd inst., when a large gathering of members and of the profession was present. The Senior President, Dr Carmichael, occupied the chair, supported by the Vice-Presidents, Mr Crerar and Dr Rainy, as croupiers. The Lord Justice Clerk and Sir Dyce Duckworth supported the President, who was the guest of the evening. Sir Dyce Duckworth proposed the toast of the Royal Medical Society and, in the course of his speech, referred to his long connexion with the Society as a former President and as one of its honorary members. Referring to the new ordinances of the

Scottish Universities Commission, he criticised the proposal to cut down the stipends of the professors in medicine, surgery and midwifery. With the decay of the University faculty in Edinburgh would inevitably come that of the great extra-academical school, which was so valuable a training ground for the professors of the future. And who, he inquired, was to benefit from the surplus fees won by the hard labours of the eminent man who conferred renown on the school? Professors of the subjects specially selected for this treatment required of all others large practice to enable them to teach with efficiency, but the gains from this source could never be very large in Edinburgh. In America they understood these matters in a very different sense, and made their University chairs prizes and objects of ambition. He characterised the new ordinance as nothing better than a proposed endowment of mediocrity. Referring to the proposals to promote special studies in certain departments, he vigorously condemned them. Indeed, he declared that the public was already demoralised by specialism and the profession somewhat degraded from its rightful position by it, and he urged his younger hearers to become great general physicians and great as great surgeons, sound and "all round" practitioners of all parts of the one and undivided healing art, and not petty with the pettiness of specialism.

THE DENTAL HOSPITAL OF LONDON

SOME months ago the Medical Committee of the Dental Hospital were impressed with the conviction that the building in which so much useful work had erstwhile been carried on was inadequate to its demands. Various inconveniences had for long been experienced in consequence of the want of proper accommodation for the medical officers and the school attached to the charity, as well as for the patients who resorted to it. It was therefore determined to seek means by which a building more worthy of its purpose than the one already in existence might be raised, and at the annual meeting of the friends and supporters of the institution, held this day (Friday), it was announced that the project had assumed a form which gives fair hopes of its realisation. The committee of management have decided to purchase, indeed have already secured, a new site for the purpose. A new hospital and the site (on the south side of Leicester square) will, it is estimated, cost something like £40,000, towards which sum something like £6000 have been raised or promised. It is to be desired that the appeal which the committee has issued may be liberally responded to, and that the hopes of the friends and supporters of the institution may in this matter be quickly and satisfactorily realised.

OUR SCHOOLMASTERS AND PERSONAL HYGIENE

WE would call attention to an excellent address delivered by the Rev J E C. Weldon the head master of Harrow, to the Birmingham Teachers' Association, which is published *in extenso* in the *Contemporary Review* of this month. We need not enter upon the teacher's self training and self discipline from the moral, social and intellectual side. It is with the physiological or health side that we are concerned, and from this standpoint we are impressed with the wisdom and common sense of the advice that is given. As regards the importance of observing the laws of health, it is very pertinently pointed out that if good temper is essential to courtesy, good health is essential to good temper. "To be well is often the true secret of teaching well. Fatigue conduces to futility. Indigestion is the mother of indiscretion. A weary schoolmaster or schoolmistress is a dreary one." The importance of a good night's rest is dwelt upon. A teacher ought always to be at his best, and time spent in sleep is a good investment—at least for all who work hard, "it is all up with him if he takes a doze in school." Again, if Nature

demands sleep she also demands exercise. The demand may be refused or ignored, but retribution is sure to follow. According to the Rev J E C Weldon's experience, payment with heavy interest is claimed about the age of fifty. "The man who has taken no exercise breaks down. A breakdown is not a break up, he resumes work after a time, but he is never again the same man." There are so many forms of exercise nowadays that it is comparatively easy for a teacher to guard against the evils of too sedentary a life. The remarks on the proper use of holidays, on rest and change, on the cultivation of a variety of interests, on the avoidance of a narrowness of mind, on the advantages of large and lavish reading and on novel reading as a means of taking people out of themselves, which is often, perhaps, the best holiday they can have, if not altogether new, have, in our opinion, the merit of being altogether true. The peril of reading no novels is alleged to be much more serious than that of reading too many. On these and several other subjects we consider that much wholesome and wise counsel is given which is likely to prove helpful to those concerned, and to those who reject or disregard it we can only say that we are sorry for them, and still more sorry for their pupils.

AN INCENTIVE (I) TO LIFE-SAVING

AT an inquest held by the Southwark coroner, at Guy's Hospital on the 7th inst. a witness who recovered the body of a young woman, in whose case animation was subsequently restored for a few hours, asked the coroner whether he would be allowed the fee for recovery of a body. The coroner informed the applicant that the fee was only paid to a person recovering a dead body in a navigable river. The deceased was alive when taken out of the water and the witness was therefore not entitled to remuneration. The applicant said that he had spoiled a suit of clothes in endeavouring to save the young woman. Had he been a few minutes later in reaching the deceased, life would have been extinct and he would have been entitled to the fee. Comment on the above mentioned monstrous state of affairs might be summarised in Dominic Sampson's exclamation, "Prodigious!" We feel constrained, however, to add that "something is rotten in the state of" England's laws which permits such a glaring anomaly to be perpetuated at the close of the nineteenth century.

CRIME, SENTENCE AND SUSPENSE

THERE is no stronger proof of the essential and inseparable connexion which exists between the medical profession and all that concerns the moral and physical health of man kind than the frequency with which the opinion of its members is sought in relation to the origin, processes, detection, punishment and prevention of crime. We need hardly point to the familiar question of sanity by way of illustration. All our modern prison usages, our means of punishment, our methods of reform, likewise imply and indicate the same vital connexion, and thus exemplify so many remedial agencies intended not so much to dispose of a dead monster of convicted guilt as to reach and combat its still living forms. Nor is this beneficent influence traceable only through its physical manifestations. It operates also at all stages of the criminal descent by mental and moral processes, and even in the presence of death combines its friendly offices with those of the more strictly spiritual adviser. This last phase of its usefulness has recently been discussed in some detail by a correspondent, who draws our attention more especially to one particular point in the history of retribution. He objects, and with reason, to the frequently long duration of suspense in which many a prisoner who is aware that efforts are being made to obtain a mitigation of the death penalty

is allowed to remain until almost the hour appointed for his execution. He would have the public, the medical profession, and especially those in authority, realise what is implied in an interval of two or three weeks thus passed in mingled hope and fear, its numbing influence on any movement towards confession or on any process of self preparation for the final change, which excludes all earthly interests. How much more merciful it would be, he says, if the final Yea or Nay of Her Majesty's representative were communicated to the doomed offender at an early date after his conviction by the jury. No words of ours are needful to commend the justice of these observations. We trust that they will not be overlooked by those with whom rests the power to give them practical effect. We may here, however, be allowed to question whether petitions for the mitigation of sentences do not sometimes themselves constitute an avoidable difficulty in arriving at that early decision which in this matter is so desirable. Most people can recall the memory of cases in which the petitions prepared were clearly certain of rejection, and the fate of such may serve as a needed check upon the impulses of a false public sentiment.

THE DESTRUCTION OF CARBAMIC ACID BY THE LIVER

IN the last part of the *Archives des Sciences Biologiques* Drs Hahn, Massen, Nencki and Pawlow give an account of an interesting investigation following up previous researches by Dr Eck in 1877 and Dr Stolnikow in 1882 on the effects produced on the animal economy by diverting the portal blood into the vena cava so that it should not supply the liver. Sixty animals were operated upon, all being narcotised. Of these, forty succumbed to accidental causes. Those that survived underwent a complete change of character, from being quiet and docile they became troublesome and obstinate, and in some cases violent and dangerous. They also suffered from repeated clonic convulsions, followed by coma, during which latter state any irritation frequently caused the convulsion to reappear. In some cases the convulsions proved fatal, they could also usually be provoked by giving the animals ment. A very striking fact observed in all the animals was the presence of a considerable amount of carbamic acid in the urine—a circumstance which led the writers to surmise that this might be the factor producing the peculiar conditions observed. To determine the point a number of experiments were made on healthy animals by introducing carbamate of sodium or calcium into the circulation. These appeared to warrant the conclusion that the toxic action observed in the first series was due to carbamic acid, and that the liver has amongst other functions that of transforming the carbamic acid which collects in the blood in normal conditions into urea.

THE BRESSA PRIZE

THE Turin Academy of Sciences, in the terms of Dr Cesare Alessandro Bressa's will, announces that the competition for the prize for the best scientific work and discoveries made in the four years from 1889 to 1892—a competition restricted to Italians—closed on Dec 31st, 1892. Now, however, the competition for the ninth Bressa prize is open, and scientists and inventors or discoverers of all nationalities are invited to come forward. The conditions are thus stated: "The prize will be awarded to the person, whatever his nation who during the quadrennium 1891-94, in the judgment of the Turin Academy of Sciences shall have made the most remarkable and most useful discovery or produced the most distinguished work in the fields of physical and experimental science, of natural history, of mathematics pure and applied, of chemistry or of physiology and pathology, not excluding geology, history, geography or statistics."

ability, and others not less fit for the work of organisation. Professor Paghani is its president, and under his energetic auspices circulars inviting the contribution of specimens of every kind of medical *matériel* are now ready for transmission to pharmacutists, surgical instrument makers, food manufacturers, wine growers, mineral water agents—to all, in short, who cater for the professional requirements of the practitioner. Many of these specimen contributions, indeed, are on their way to the 'Esposizione,' their contributors being, not unnaturally, interested in securing an advantageous *locale* for their contributions. The alimentary and wine departments will, I have good reason to know, be richly represented not only by Italian purveyors and by British houses established in Italy, but by those of other nationalities—Swiss, Austrian and German in particular. For all contributors from abroad the Commendatore Paghani is exerting his great influence—parliamentary, social and professional—to secure facilities for the convenient consignment of their wares *en route* to the Exposition by reducing railway charges and minimising Custom House formalities to the vanishing point. That the 'Esposizione' shall be 'la nota saliente' (the outstanding feature) of the Eleventh International Congress of Medicine and Surgery is the avowed object of the Commendatore Paghani and his coadjutors on the committee, and certainly they are sparing no effort to be as good as their word."

EMPLOYMENT FOR THE BLIND

WE may safely say that, with the exception of those mentally afflicted, no class of the population have suffered so much from the want of employment entailed by their condition as the blind. They have not, indeed, been left altogether without means of livelihood, and some few, favoured by social position and means, have attained to the discharge of great and useful functions. As a rule, however, the blind man's calling has consisted merely in the practice of some simple handicraft requiring for its exercise only the most moderate amount of intelligence. Of late years a change has begun to come about. Much has been done by means of specially directed education to increase the intellectual and practical energy of this once neglected class and thus to justify their occupation in work of a more complicated and responsible character. There exists in consequence a need of such employment, so modified and adjusted that the sense of sight shall not be indispensable to its exercise, and indications are not wanting to show that the demand may be satisfied. As an illustration we may mention the recent introduction by Mr F W Smith of Brighton of a typewriter intended for the use of blind persons which prints embossed characters and is adapted to any type. This invention, we repeat, is noteworthy, not only for its own sake, but as indicating the growth of a purpose which promises to bring more and more within reach of the hitherto incapable blind a considerable part at least of the privilege of work enjoyed by their seeing neighbours. We might suggest the telephone and even the telegraph systems as other possible outlets for their energies.

ANNUAL DINNER OF THE ROYAL MEDICAL SOCIETY OF EDINBURGH

THE dinner of this Society was held in the Waterloo Rooms, Edinburgh, on the 3rd inst., when a large gathering of members and of the profession was present. The Senior President, Dr Carmichael, occupied the chair, supported by the Vice-Presidents, Mr Crerar and Dr Rainy, as croupiers. The Lord Justice Clerk and Sir Dyce Duckworth supported the President, who was the guest of the evening. Sir Dyce Duckworth proposed the toast of the Royal Medical Society and, in the course of his speech, referred to his long connexion with the Society as a former President and as one of its honorary members. Referring to the new ordinances of the

Scottish Universities Commission, he criticised the proposal to cut down the stipends of the professors in medicine, surgery and midwifery. With the decay of the University faculty in Edinburgh would inevitably come that of the great extra-academical school, which was so valuable a training ground for the professors of the future. And who, he inquired, was to benefit from the surplus fees won by the hard labours of the eminent man who conferred renown on the school? Professors of the subjects specially selected for this treatment required of all others large practices to enable them to teach with efficiency, but the gains from this source could never be very large in Edinburgh. In America they understood these matters in a very different sense, and made their University chairs prizes and objects of ambition. He characterised the new ordinance as nothing better than a proposed endowment of mediocrity. Reverting to the proposals to promote special studies in certain departments, he vigorously condemned them. Indeed, he declared that the public was already demoralised by specialism and the profession somewhat degraded from its rightful position by it, and he urged his younger hearers to become great great physicians and great great surgeons, sound and "a round" practitioners of all parts of the one and undivided healing art, and not petty with the pettiness of specialism.

THE DENTAL HOSPITAL OF LONDON

SOME months ago the Medical Committee of the Dental Hospital were impressed with the conviction that the building in which so much useful work had erstwhile been carried on was inadequate to its demands. Various inconveniences had for long been experienced in consequence of the want of proper accommodation for the medical officers and the school attached to the charity, as well as for the patients who resorted to it. It was therefore determined to seek means by which a building more worthy of its purpose than the one already in existence might be raised, and at the annual meeting of the friends and supporters of the institution, held this day (Friday), it was announced that the project had assumed a form which gives fair hopes of its realisation. The committee of management have decided to purchase, indeed have already secured, a new site for the purpose. A new hospital on the site (on the south side of Leicester square) will, it is estimated, cost something like £40,000, towards which sum something like £6000 have been raised or promised. It is to be desired that the appeal which the committee has issued may be liberally responded to, and that the hopes of the friends and supporters of the institution may in this matter be quickly and satisfactorily realised.

OUR SCHOOLMASTERS AND PERSONAL HYGIENE

WE would call attention to an excellent address delivered by the Rev J E C Weldon the head master of Harrow, to the Birmingham Teachers' Association, which is published *in extenso* in the *Contemporary Review* of this month. We need not enter upon the teacher's self training and self discipline from the moral, social and intellectual side. It is with the physiological or health side that we are concerned, and from this standpoint we are impressed with the wisdom and common sense of the advice that is given. As regards the importance of observing the laws of health, it is very pertinently pointed out that if good temper is essential to courtesy, good health is essential to good temper. "To be well is often the true secret of teaching well. Fatigue conduces to futility. Indigestion is the mother of indiscretion. A weary schoolmaster or schoolmistress is a dreary one." The importance of a good night's rest is dwelt upon. A teacher ought always to be at his best, and time spent in sleep is a good investment—at least for all who work hard, "it is all up with him if he takes a doze in school." Again, if Nature

appointment filled by an Austrian. For the present the duties of the chair will be undertaken by Dr F Kraus, *dozent in Medicine*

SOME little commotion arose at a meeting of the City Commissioners of Sewers on Monday by the reading of a communication from the Thames Conservancy Board in reference to the proposal of the Commission to place a temporary floating hospital on the Thames between London and Southwark bridges. It appears that parties connected with the traffic on the river are strongly opposed to the proposition on account of the problematical danger which might result to the riparian population. In the end the letter was referred to the Sanitary Committee.

AN inquiry was held on Tuesday and Wednesday last by Mr Hedley and Dr Downes, Inspectors of the Local Government Board, at Tooting, in reference to the proposal of the Metropolitan Asylums Board to erect an infectious diseases hospital at Tooting Common. The Asylums Board and the opponents of the scheme were respectively represented by counsel. After the examination of several witnesses the inquiry was concluded.

DR. GIUSEPPE LAPPOSI has been appointed, by special decree, *Archiatro Pontificio* (consultant in chief to the supreme Pontiff), in succession to Dr Alessandro Ceccarelli, deceased, and (also in succession to Dr Ceccarelli) he has been nominated *Direttore dell' Ufficio d'Igiene dei Palazzi Apostolici* (Sanitary Director of the Vatican and Lateran Palaces and of Castel Gandolfo, the summer residence of the Popes).

THE Port of London Sanitary Authority has just issued by laws providing for the removal from vessels within the port of persons who shall have been found to be suffering from infectious diseases accounted to be dangerous and a list of which is scheduled. Breach of these by laws renders the offender liable to a penalty of £5, with a further fine of 40s a day after notice has been given by the authority.

ON our account last week of the annual general meeting of the Royal Medical and Chirurgical Society we omitted to mention that the Fellows, upon the recommendation of the Council, unanimously awarded the Quinquennial Marshall Hall Prize of £80 to Dr W. R. Gowers for his original work in relation to Diseases of the Nervous System.

IN consequence of the numerous applications for tickets of admission to the Croonian Lecture of the Royal Society, which is to be delivered by Professor R. Virchow at 4.30 P.M. on the 16th inst., it has been decided to hold the meeting in the theatre of the London University, which has been kindly lent for the occasion by the Senate.

DR. THORNE THORNE, C.B., medical officer of the Local Government Board who has been appointed as a British delegate to the International Sanitary Conference, left London on Tuesday last for Dresden. He will be assisted by Mr H. Farnall of the Foreign Office. Dr Thorne, it will be remembered acted in the same capacity at Paris in 1889.

RAGNIT, in Eastern Prussia, has says Dalziel's agency been visited with a malignant epidemic. The plague is daily increasing in intensity and all the schools have been closed.

ON Monday last, March 6th, Sir Joseph Lister was elected a Foreign Associate of the Academy of Sciences of the Institute of France.

LORD SANDHURST, Under Secretary of State for War, opened the new infirmary at the Royal Arsenal, Woolwich, on the 8th inst.

THE meeting of the British Association next year will be held at Oxford, and will have as its President the Marquis of Salisbury.

Pharmacology and Therapeutics.

METHYLENE BLUE IN MALARIAL FEVER.

METHYLENE BLUE, which had been recommended as a remedy in malarial fever by Guttman, Ehrlich, Bourdillon and others, has recently been systematically tested by Professor Parenski and Dr Blatteis of Cracow, who state that in thirty three cases of malarial fever out of thirty five a complete cure was obtained by its means. It was administered sometimes by the mouth in the form of powders six or seven grains being ordered two or three times daily, and sometimes hypodermically, a Pravaz syringe of a 10 per cent. solution being injected twice a day. These injections caused but little pain and in no case gave rise to suppuration. When given by the stomach vomiting was sometimes produced at first, and if the doses were large, some discomfort in passing urine was experienced, which however, was readily combated by the simultaneous administration of carbonate of magnesia. Another well known effect of the drug was to colour the stools blue, while the urine became green and the sputa and perspiration partook somewhat of the same tint. The therapeutic action manifested itself by a beneficial effect on the febrile attacks on the hypertrophy of the spleen, on the number of plasmodia and on the various symptoms accompanying the fever. The febrile attacks generally ceased after from three to five hypodermic injections, after from three to six doses of methylene blue the spleen rapidly decreased in size, the plasmodia often disappeared from the blood after two or three doses, and the accompanying symptoms such as headache and gastralgia yielded more quickly to methylene blue than to quinine. Dr Moncorvo has also been employing methylene blue in malaria. In all cases the patients bore the drug well. There was never any diarrhoea, polyuria or albumuria, as some observers have reported. In one case however, there was some transitory vesical tenesmus. Dr Moncorvo remarks that the tastelessness of the aniline derivative has much to recommend it in the case of children, quinine being difficult to administer.

THE MANUFACTURE OF NITRO BENZOL AND DI NITRO BENZOL.

The risks arising in the manufacture and handling of nitrobenzol and di nitro benzol and the precautions which should be adopted form the subject of an interesting report to the Secretary of State for the Home Department by Dr Dupré and Commander Hamilton P. Smith, R.N. Attention has recently been drawn to the subject by various writers notably by Dr R. Prosser White, of Wigan. In the report before us after a brief description of the mode of preparation and the physical properties of the pure substances Dr Dupré and Commander Smith state that the ordinary commercial di nitro-benzol generally contains a greater or lesser amount of impurities and that these considerably increase the danger incurred in working. This may be because their vapours are poisonous, but it is more probably because the impure slightly greasy di nitro-benzol adheres more readily to the fingers and is more easily absorbed through the skin. It is suggested that manufacturers of explosives should, if possible, use only di nitro benzol, which is practically free from smell which produces no greasy stain when rubbed on paper and which does not sensibly volatilise at ordinary temperatures. Dr Dupré and Commander Smith are of opinion that although nitro benzol taken internally acts as a poison, no injury to the health of the workers in the manufacture of nitro-benzol results with the ordinary precaution of sufficient ventilation. Abundant evidence of a negative kind seems to prove that exposure to the fumes of nitro-benzol is not attended with danger. With the di nitro-benzol however, they have arrived at very different conclusions confirmatory of the opinion that this substance is a dangerous poison to workers who handle it or who inhale fumes or dust in places where it forms an ingredient in the manufacture. Masters and men

The competition closes on Dec 31st, 1894. The sum set apart for the prize, after deducting the Italian income tax (*ricchezza mobile*), amounts to 10,418 fr (£418 13s 4d). All competitors must, within the above named period, communicate by letter with the President of the Academy and at the same time present the works with which they intend to compete. The work must be printed, manuscripts being excluded from consideration. The unsuccessful works will be returned to their authors on a special request made within six months from the adjudication of the prize. No Italian member of the Academy, resident or non resident, can compete or receive the award. The Academy reserves its right to bestow the prize on the "most worthy scientific man," although he may not have entered the competition.

MUSIC AS AN AID TO MEDICINE

MUSIC, which has of late been sending forth new trial shoots in the field of therapeutics, was again brought under the notice of the profession in this connexion by Dr J G Blackman in the January number of the *Medical Magazine*. Defined by this author as the language of sounds, its effects are briefly stated to consist in the production of motion, with liberation of nerve force and a generally pleasant result. The observations of Dogiel are again quoted as proving its regulating effect upon the circulatory system and its consequent close relation to tissue nutrition. It is doubtless in this way that its exhilarating or calmative influence in conditions of mental disease may best be explained. The article above mentioned is interesting to us as conveying the first definite statistical evidence we have met with respecting the employment of music in clinical medicine. The observations of Dr J Ewing Hunter at the Helensburgh Hospital go to show that amongst the obvious effects of its use relief of pain has in many cases been most marked, and we are also informed that rapid reduction of temperature in a case of peritonitis appeared to have a similar origin. Of course we must in all such cases make due allowance for the possibility of a *post* and *propter hoc* fallacy and we should certainly exceed every known sanction of science if we were to claim for music a distinctly curative influence in organic lesions. Nevertheless the fact remains that healthy nerve tone has much to do with tissue nutrition and that music as a recognised agent in its production has thus far a place—albeit a subordinate one—amongst the extra pharmacopœial remedies available for the purposes of the physician.

PARASITIC ORIGIN OF CANCER

THE last two sittings of the Pathological Society have been occupied with an interesting discussion on a paper by Mr Jackson Clarke dealing with the parasitic origin of malignant cancer and sarcomatous diseases. In recent years the evidence on this point has been gradually growing stronger and stronger, and the attention of pathologists has been more and more drawn to the consideration of certain forms of organisms that have been described as present in cancer. Scheuerlen first ascribed the symptoms of irritation to the presence of a bacillus—a bacillus which we now know is frequently met with in the skin and probably plays little part as an active etiological factor in the production of cancer, then more recently it has been supposed (1) that budding fungi, (2) that psorosperms, or some similar parasite, might play a part in setting up the necessary process of irritation in cancer. Now, however, we find an observer coming forward to state that in both cancer and sarcoma an enormous number of spore bearing organisms and free spores may be demonstrated in every specimen in these malignant growths. He maintains that they are not mere dividing protozoa but that they are more or less closely related to the spore bearing psorosperms. Such a contention naturally met with very considerable opposition, as

its acceptance is almost equal to postulating that a large proportion of such tumours, hitherto recognised as being degenerated cells, giant cells and invading leucocytes, must be looked upon as being parasitic psorosperms in various stages of development. Whatever the immediate outcome of the discussion may be, it can ultimately lead to nothing but good, as it will necessarily draw the attention of a considerable number of histologists to an aspect of the pathology of malignant disease which, though studied by individual observers, has not yet been generally considered.

THE LATE DR HAYES AGNEW

In the *University Medical Magazine* for February, 1893, is published a Memoir of the late Dr Hayes Agnew, prepared by Dr J William White and read before the College of Physicians of Philadelphia. Dr White was for many years closely associated with Dr Agnew in both hospital and private work and had the best opportunities of becoming thoroughly acquainted with him. His highly appreciative memoir will be greatly valued by the large number of surgeons by whom Dr Agnew's memory will always be cherished.

THE SALE OF STAMPED PROPRIETARY MEDICINES

AN indication of the importance attached to the decision given in the recent chlorodyne test action is to be found in a circular issued by the executive of the Federation of Grocers' Associations. This circular frankly recognises that it has been decided that no person, not being a properly qualified druggist, can legally sell "poisons," as a practical outcome a list is given of preparations which have been labeled "poison" and thus come within this decision, it is therefore recommended that they should at once be withdrawn from sale by grocers. The list comprises forty three articles and includes many sedatives, cough lozenges, syrups and vermin killers—some with familiar names, a few with titles which give no indication of the purpose for which they may be employed or of their composition. Many are preparations of active poisons which have already been credited with causing many fatalities and we are glad to see that they will no longer be retailed freely by grocers. After this distinct warning from the side of the trade it is to be hoped that the numbers of "misadventures" and "accidents" may be diminished. It is at any rate satisfactory to find that, although leave of appeal against the chlorodyne decision was granted, the members of the trade have not waited longer before taking active steps to minimise the risks to the public and also to themselves.

FOREIGN UNIVERSITY INTELLIGENCE.

Clausenburg—Dr Josef Löte has been promoted to the Ordinary Professorship of General Pathology and Therapeutics.—Drs Engel and Göth have been promoted to Extraordinary Professorships of Midwifery.

Leipzig—Drs Lenhart, Karg, and Döderlein have been appointed Professors.

Tomsk—The professors and other members of the Scientific Association have contributed several very remarkable papers, which are published in the Transactions of the Association. Great credit is given them in Russian scientific circles for the energetic way in which they have managed to carry on scientific research in a very isolated locality and with a great lack of appliances and assistance. Grave complaints are beginning to make themselves heard of the darkness and unsuitability of the rooms assigned as laboratories. The University building, too, though only five years old, is in a very defective state, large cracks in the walls having made their appearance.

Vienna—Objections have been raised to the gentlemen proposed for the vacant chair of Medicine on the score of their being foreigners and an effort is being made to get the

the detailed work. There is no resident medical or other superintendent, and the chairman of the managing committee was of opinion that much opposition would be offered to such an appointment. At the Charing cross Hospital, which is in financial difficulties, the daily management is in the hands of the secretary, who is non resident, but the chaplain is the highest resident officer, and either of them would in any serious emergency refer to one of the treasurers. At the Westminster Hospital the secretary has a general control over the establishment, but the precise limits of his authority are not strictly defined. Both he and the chaplain are non resident, and there is no resident medical superintendent. There are several committees for detailed duties.

The above are sufficient to show that the chief routine work of these institutions is performed by committees, and that the principles of procedure and action are very much the same in all. The medical staffs have little or no control over the management, and there is in no case a single responsible resident medical officer with full power, as in the Poor law infirmaries, to control and direct, subject to official inspection and audit and to the supreme authority of the guardians of the district. There is no reason to doubt that most, if not all, of these numerous and varied committees do their work fairly well, but the absence of all direct and immediate personal responsibility, I think, fatal to thoroughly efficient control and economical management, which latter appears to me to demand more attention than it receives otherwise there would not be such extensive differences in the cost of the same class of work, as Mr Burdett has shown in his most useful writings on the subject. Outside all these conditions, important as they are, is the fact that the primary function of all hospitals is the successful treatment of disease in the widest sense of the word, and the collateral and contingent benefits to the poor of which they are such beneficial agents. To this all other relations, scientific and administrative, should be absolutely subordinated.

What, then, are the cardinal conditions which ought to be observed in the executive management of all hospitals to extract the largest amount of benefit from them, in their important relations to the public and to the profession most immediately concerned in their efficiency? The question is very old and was thus answered by Sir William Blizard a century since. "The value of medical science in every walk of life, independently of its application in preventing and curing disease, should be seriously considered. All men are indebted to the discoverers and cultivators of natural truths for some share of their useful knowledge and of the felicity they enjoy. Many, therefore, are the objects interesting to society that present themselves in contemplating the professional concerns of a hospital, and as in commercial and other affairs, they will be best understood by those who have most devoted their time and attention to the subject. Every thing liberal may be expected where charity is the governing principle of action, and where the good done bears proportion to the degree of knowledge exercised. Parity of motive, sincerity of attention in the surgeons will not then be doubted. It may not, however, be improper to observe that their credit and interest are involved in all the proceedings of a hospital, for its prosperity is their interest, its depression their loss and regret."

I need not point the moral to show how injurious I consider the position occupied by the medical profession in the hospitals of London to be. The Committee whose report I am considering express disapproval of the manner of government of the endowed hospitals, and suggest a remedy which does not appear to me to be calculated to mend matters materially. Indeed, as it is tolerably certain to be objected to by those immediately concerned, it may operate injuriously in destroying the very small amount of direct personal responsibility at present in force in these institutions. As to the voluntary hospitals mentioned in the report, it was said that the systems of management greatly resembled each other, and that the evidence showed them to be generally well administered. This is doubtless correct as respects the limited scope of the inquiry, but as no records were examined, no institutions visited and none of the scientific results ascertained or recorded it must be accepted with some reserve. What appears to me to be really required is unity of executive control in skilled professional hands, under efficient administrative supervision by properly organised committees of each institution to preserve their autonomy added to independent inspection and audit, and all this can only be obtained by a radical change of system. This I shall endeavour to show in relation to the present unequal

distribution of the general hospitals of London, the total absence of all coöperation on the part of the institutions devoted to the care and treatment of the sick poor, the formation of a central board of supervision, the grouping of the hospitals in the different centres of the population of London, the federation of the clinical system, and the publication annually of a uniform system of accounts and of medical statistics, by which latter alone can the character and quality of the professional work performed be properly gauged.

The next subject referred to by the Committee is that of the admission of patients to the voluntary general hospitals—a very serious consideration to the sick poor, for whom all such places were originally established, and for whom they are still chiefly intended. Viewed from the standpoint of charity, the more recent guiding principle of admission is a distinct departure from that intention and purpose. The procuring of subscribers' letters although said to be very little resorted to now, and never so as to interfere injuriously with serious cases seeking admission at the same time, may be true, but it is a practice which ought nevertheless to be discontinued. It is a sort of benevolence which is inconsistent with true charity, from its great liability to abuse. When exercised, it can seldom be with the care and attention necessary to prevent its being bestowed upon some, at least, who are not objects of charity, and thus deprive others of beds who have a better claim to them.

If the admission of patients is faulty, still more so is their discharge, not only before cure, but when medicine has done little or nothing for them. To compel them at such a time to seek a refuge in the Poor law infirmaries, which they had endeavoured to avoid by entering a voluntary hospital, I cannot but consider a cruel proceeding, and one for which there is no valid plea of justification. To make way for a more interesting case or in any other way to subvert the interests of the institution to the manifest detriment of the sick I look upon as unjustifiable, and amongst the practices which are regarded by the French as inhuman in our system. Another proceeding of a similar character is, I think, almost as objectionable—viz, fixed days for admissions and discharges. These practices are, I believe, largely due to the operation of the voluntary system, inasmuch as in very many appeals for fresh subscriptions or funds urgently needed the large amount of cases treated is urged as a strong claim for more pecuniary aid. This is no test of the value of the work done or for determining its merits, as it would falsify the statistics of the institution were they prepared and published as they ought to be. MM Blondin and Sere, in contrasting the procedure of the two nations and particularising the peculiarities of the voluntary system, observe that English measures of relief are controlled to a great extent by the privileges of subscribers and donors and the sources generally of their incomes, whilst those of France are aimed only at providing the most complete succour and thus effecting the greatest possible good with it. The discharges from French hospitals are regulated with special care, to prevent the abuse of the resources of the hospital without prejudice to cases which need more prolonged care before discharge or transfer to one of the State convalescent asylums. I am of opinion that the imperfections of our system are susceptible of amendment by reconciling private and public charity in relation to disabling sickness where that is the cause of the temporary poverty that drives many honest persons to seek relief in institutions to which no civil disabilities are attached.

The last branch of this portion of the report of the Select Committee is the out-patient system, which has excited so much attention, and in which such extreme divergence of opinion existed. This divergence was so marked and most of the views so impossible to reconcile as to cause the Committee to formulate and discuss each of the contentions for and against the system in force. To consider these in detail, with the hope of extracting from them any leading principles to guide us in producing a complete working scheme, would, I think, be an unprofitable task, even were it practicable. The main objections entertained were, I think, established—viz, that either as instruments of relief or as measures of medical training the overwhelming numbers who crowded the out-patient rooms rendered the whole proceeding one of questionable value, even when not used for purposes of inflation, as baits for subscriptions, as injurious to the sick from hasty examination, incorrect diagnoses, or erroneous treatment, as characterised by want of discriminating persons able to pay for treatment, as stifling pro-

alike recognise the danger of the fumes in the manufacture of di nitro-benzol, and the precautions which are accordingly adopted appear to be adequate. The chief danger seems to lie in the fumes of di nitro benzol when it is used as an ingredient in the manufacture of explosives and when it is employed by the workers in mines. The precautions recommended consist partly in the careful selection of those who are physically fit for such employment, and they otherwise relate to efficient ventilation and to measures calculated to prevent absorption by the skin or by the respiratory passages. When di nitro-benzol has to be handled it is advised that the hands shall always be protected from direct contact with it either by the use of indiarubber gloves (kept perfectly clean, especially on the inner side) or by means of rags which can be destroyed after use. The whole report is reassuring in showing that the dangers are fully realised by all concerned in dealing with these substances and that adequate provision is generally adopted to minimise the risks.

CAUTION RESPECTING SULPHATE OF COPPER IN GYNÆCOLOGY

Sulphate of copper has been strongly recommended as a local application in endometritis by Dr Dumontpallier, who believes that it is superior to chloride of zinc, as it only produces superficial cauterisation, and according to him has no tendency to cause ultimate atresia of the os. He employs an elongated suppository made of equal parts of sulphate of copper and oatmeal. According to M Matignon, who recently read a paper on the subject before the Bordeaux Medical Society, sulphate of copper is by no means always so mild in its action as Dr Dumontpallier believes. In one of his cases, where a suppository containing seven grains and a half of the copper salt was inserted, the patient experienced four days afterwards severe uterine colic and vomiting, a quantity of false membrane was passed, in which microscopical examination showed all the elements of the uterine mucous membrane together with those of the subjacent muscular tissue. This was followed by a very perceptible diminution in the size of the cervical canal and also by a severe inflammatory attack in the uterine appendages. In two other cases where similar treatment was employed there was evidence of the caustic having destroyed the whole thickness of the mucous membrane and part of the muscular coat, some degree of atresia following. Notwithstanding these occasional inconveniences M Matignon does not suggest that sulphate of copper should be abandoned, as he finds it most useful in leucorrhœa, but he says that not more than three grains and a quarter should be used in the suppository.

ON THE ORGANISATION OF MEDICAL RELIEF IN THE METROPOLIS

By F J MOUNT, LL D, M D EDIN, F R C S ENG

III

It was my intention to have examined and analysed every branch of the system of management of the hospitals of the metropolis in the order observed in the able report of the Lords' Committee, but on carefully sifting the voluminous evidence I find that it will be impossible to do so in a reasonable compass, as much of that evidence is of little value, and it would be difficult to elaborate from it a practicable scheme to fit the varying conditions deemed necessary to remove the evils complained of. In the commencement of the report is given a brief outline of the present form of government and financial resources of each of the twelve most important endowed and voluntary hospitals within the area of the inquiry. The pervading principle of action in most of them is an administration by committees with no authoritative single resident executive chief to deal decisively with each contingency as it arises. The essence of authority in purely executive matters is to be one and indivisible. In some of them the ruling power is a lay treasurer, practically an autocrat, yet nominally subject to the controlling authority of various committees, with no connecting bond of action to secure continuity of procedure, and in which the lay element is so predominant that the trained and skilled professional agency by which the higher work of the institution is performed has no potential voice in its control and government. In noticing the endowed

hospitals it must be remembered that they are subject to the conditions of special charters which may possibly in some degree fetter their action and cause the retention of ancient practices which are not in harmony with existing views and circumstances. The records of these institutions, however, do not appear to have been examined by the Committee, and the accounts given by the authorities of each were not subjected to any special scrutiny to verify their accuracy. St Bartholomew's Hospital has a governing body of 273 members, self elected, with elaborate machinery for its management, in the real control of which its distinguished medical staff appears to have no place. The highest authority is the treasurer, who is non resident, and, although a most able and distinguished administrator, can scarcely have sufficient time for the thorough discharge of the important and onerous duties assigned to his office. At St. Thomas's Hospital the principal officers (apart from the medical and nursing staff) are a resident treasurer, who is the head of the institution, a receiver and a steward. There is a medical committee, comprising the medical staff, which meets once a week as a rule. All matters connected with the school come before them, and they recommend students to the treasurer and almoner for appointment to offices in the hospital. There is also a house committee, on which there are two retired medical officers on the consulting staff, together with the dean and senior physician and surgeon, who attend as consultants, but are not members of the committee. In the administrative government of this great hospital and school the professional staff has no real power.

Their lordships have pronounced it to be one of the model hospitals of the world—a view that is not generally taken by those who have spoken with authority on the subject. It is magnificent in its palatial construction and arrangement, but in this and other respects is more rightly regarded as a model to avoid than to imitate. In fact, the most recent leading hospitals of London and Paris are the greatest failures of our time, but, as this is the only point of hospital construction noticed by the Committee, it is not necessary to go further into the matter. Palaces are not required for the sick poor, more especially since the practical extinction of hospitalism in surgery by the discoveries of Lister and in medicine, scarcely in a minor degree, by the labours of Pasteur and others. Guy's Hospital is exceptional in many ways, and although it has a resident medical superintendent he has no strictly medical duties to perform, his function being to act as an aid to the treasurer. With an income considerably reduced by the lowered value of its landed property it has still an annual command of £26,000 with which it is unable to fill its beds, and therefore some short time since raised £100,000 apparently to enable it to do so. This sum is employed in instalments for its current wants, and might, I venture to think, have been more profitably used in adding to its permanent resources. It has likewise paying patients and a small addition to its funds by a trifling fee levied on out-door patients. It is in reality under the control of an able resident treasurer, who has several consultative committees to assist him in its management, but in practice his authority is absolute, and his views, as contained in his evidence, have been moulded in an entirely different and higher sphere of action.

Apparently with a view to remedy some of the anomalies of management, and considering the power entrusted to the treasurers to be too great, the Committee suggest that "in all these endowed hospitals the management should be carried on by a system of weekly boards and subcommittees," a proceeding which may possibly mitigate some of the defects of the existing system of control, but does not touch the root of the evil.

One or two examples of the manner in which matters are managed in some of the voluntary general hospitals will be sufficient to indicate the procedure of the whole of them, as the principle of action is very much the same, and the variations mere details adapted to local circumstances. At King's College Hospital the secretary, who is also at present the chaplain and warden and is non resident, is the head officer and has supreme controlling authority in the absence of a committee of management of twenty-four governors elected at the annual court. Of this committee the Principal of King's College Hospital and the treasurer are official members, and some members of the medical staff are always on it. There is also a medical committee of the whole staff, who are said in general to take no active part in the management. There is a variety of other committees for

general management of the hospitals the public will lose their chief interest in those institutions, that their subscribers and supporters would fall away, and that the working classes would cease to exercise thrift in providing against sickness, even to the extent to which they now practise it in becoming members of sick clubs and friendly societies. I hope and believe that this would not be the case. There is not the same indisposition to resort to a hospital that there is to enter a workhouse, and if they were assured of timely aid when it is needed and welcome, without wasting hours and some times days, in endeavouring to procure subscribers' letters, they would soon learn to contribute to its maintenance as a harbour of refuge in their own hour of trial. It is also, in my opinion, an absolute delusion to imagine that our most intelligent artisans, and even those lower in the social scale than themselves, are not alive to their own interests or that they are possessed of erroneous notions of social economy in relation to their immediate surroundings. It is the class immediately above them who appear to crowd the outpatient department and apply for in-door relief, and what can be more demoralising and destructive of every feeling of self restraint and self respect than those seeking gratuitous medical aid under a false pretence of poverty?

It would, I think, be an undeserved reflection upon those better off in the world to suppose that they would close their hearts and their purse-strings to appeals properly prepared on behalf of the hospitals, even if a part of the burden of support were borne by the community at large through the agency of the State. The really unselfish and benevolent are the few, the selfish and indifferent are the many. The whole cost of maintenance falls upon the former. Any plan then that would distribute the duty fairly among all bound to contribute to it in a manner which admits of no evasion would enable the really charitable to continue their present efforts with a better chance of success than now obtains. There will always remain a wide margin of distress which no public agency can touch, and which must for ever remain the privilege of those whose ears are always open to the cry of anguish and whose hearts are moved to its relief by the agency of personal sympathy and support.

In my next communication I propose to deal with the question of coöperation from the scientific side.

CHOLERA.

THE absence of news about any extensive prevalence of this disease at the present time is satisfactory. That it still prevails however, to some extent in Russia is no doubt true, but no official statements or reports have reached us since those published in the *Official Gazette* to which we referred last week, as to there being signs of its wide diffusion in that country or of its presence in frontier provinces like Podolia and Kieff.

As regards the Dresden International Conference, some political difficulty has, it appears arisen in Roumania owing to the action of Austria and Russia in insisting that the question of the Danube ports quarantine regulations shall be discussed. Roumania is very sensitive about her rights on the Danube, and the Roumanian Government have urged that its position and jurisdiction in regard to these quarantine regulations should be finally settled first of all. The matters to be discussed at the Conference are of international interest and for the welfare of all in common, and it is therefore highly probable that a satisfactory understanding will be arrived at and that all the Powers interested—as they all are—will take part in the Congress.

CHOLERA IN FRANCE

(FROM OUR SPECIAL CORRESPONDENT)

A VISIT TO PORTEL.

English Visitors at Boulogne—Tourists at Portel—Resistance to Sanitary Measures—Contamination of Wells and Streets—High Cholera Mortality

THERE is probably no town outside England better known to the English than Boulogne-sur-Mer. The number of English visitors and residents at this agreeable sea bathing station is exceptional. The town is within an hour's railway

journey of Calais, and *via* Folkestone is less than five hours' journey from London. Communications between London and Boulogne are frequent and easy. The Londoner who spends his holiday at Boulogne can enjoy the advantage of going abroad whilst incurring but little trouble or expense and remaining within easy reach of London. This, combined with the attractions of the picturesque old town, the Casino, and the magnificent sands, contribute to render Boulogne the most popular French bathing place for English visitors. It would therefore prove a matter of more than usual concern should a severe cholera epidemic break out there. Unfortunately Boulogne has not been exempt from some cases of cholera, and at Portel, which may be considered one of its suburbs, there has been a very severe epidemic. Portel is a picturesque village on the coast, little more than three miles from Boulogne. Indeed, with the exception of a distance of about 500 yards, the whole of the road from Boulogne to Portel is lined with houses. The connexion between the two places is the closer from the fact that Boulogne is the port for Portel and the majority of the inhabitants of the latter place are engaged in fishing. The Portel fishing smacks bring their fish to the Boulogne harbour, and the Portel fishwives meet the boats and help to unload them. The road between Portel and Boulogne is peopled with the fishing population going backwards and forwards from their boats in the Boulogne harbour to their homes at Portel. It was therefore a very serious matter for Boulogne when cholera broke out at Portel. Many of the visitors to the former make excursions to the latter place. Portel has a fine beach surrounded by high cliffs. Here the bathing is free, a fact which does not fail to attract a good many people. A few families come and spend their summer holidays at Portel, where the cost of living is much cheaper than at Boulogne and where lodgings of a very modest description can be found in the houses of some of the inhabitants. Most of the houses are more like cottages, having but one or occasionally two storeys. They are whitewashed, but often colour is mixed with the whitewash, so that there are light blue, green, yellow and brown houses, all of them enlivened with very bright green shutters. The roofs are tall, of red tile, with attic windows, and the houses have very frequently but one floor, the ground floor, unless there be a cellar, though it is difficult to account for such cellars, as land is cheap and it would be much better to build the houses a storey higher. Still, there are cellars and these are not only used for lumber &c., but are sometimes inhabited. The beach is reached by steps cut in the rock or by a winding footway which follows a stream or small torrent that debouches into the sea in the centre of the little bay where the sand has accumulated. On all sides gutters converge upon the beach or into this stream. The declivities are steep and the water rushes along the gutters bearing to the sea rubbish of all sorts, fragments of fish and vegetables, soapsuds and the fresh blood and offal from small private slaughterhouses. Children are to be seen in all directions playing on the sandy soil of the streets and floating paper boats in the dirty gutters. The first case of cholera is stated to have occurred on Sept. 17th, 1892, and the victim was a child only four months old. The second case was also that of a child, a girl nearly three years old. There had been no cholera at Portel since 1848, and many different theories were propounded to explain the recent epidemic. According to one theory the cholera was imported from Ostend where a woman from Portel had been to fetch two of her children. Her husband was taken ill as also were a friend and neighbour. The neighbour, the weaker man of the two died first but this did not occur till a fortnight after the two children had returned from Ostend. There was, however, far more cholera at Paris than at Ostend, and, if two children came from Ostend, there were several hundred visitors who came from Paris. Apart from the few persons who spend their holidays at Portel, omnibuses travel backwards and forwards daily and frequently between Boulogne and Portel. Excursionists from Paris to Boulogne profit by these omnibuses to visit Portel where they can enjoy free of cost, a dip in the sea. Out of these hundreds of visitors it is more than probable that one or more were attacked by choleraic diarrhoea whilst at Portel. The same doubtless also occurred at Boulogne, but then Boulogne is a better drained town. At Portel some of the houses have porous cesspools—*bétoires*—so built as to allow their contents to escape into the subsoil. Other houses have only small pails, which are occasionally emptied into the sea. But a great many houses have neither *bétoires* nor pails they simply throw

vident dispensaries in their vicinity, and as interfering injuriously with the rights of general practitioners, whose practice is chiefly amongst the classes who resort most to the out patients' department. There were other objections stated which do not require special mention.

That an out-patient department is absolutely necessary for the success of a hospital and that its absence would amount to a national calamity can scarcely be accepted as correct when as an instrument either of relief or instruction it is in general use in no other country than our own. Elsewhere—in Edinburgh, for example, and in some of the hospitals of the United States—there is no difficulty in filling wards with suitable cases for clinical or other purposes and in giving relief in attacks of disease which do not need hospital in-door treatment. In those countries and places as complete and scientific a medical training as in our own is afforded without the aid of such an institution. In Paris, where I have seen the practice in use, the manner in which admissions are dealt with by the Assistance Publique is far more satisfactory and complete than our own, and I have worked a system myself in a dispensary, as a source of supply to the great hospital of which I was then first physician, with perfect success. The other extreme view submitted to the Committee, that an out-patient department is absolutely useless, cannot be accepted by anyone who has a practical knowledge of the matter.

Since the professional inquiry of 1870 some amendment has been effected by restricting the numbers admitted to out-door departments and by the adoption of somewhat better means of eliminating those who have no business to find their way there, but I fear that these palliative measures will not cure the evil. The general practitioners and dispensaries are both, I think, injuriously affected by the competition of the hospitals, and I see little prospect of this being amended until the whole question of hospital management, medical education and relief of sickness connected with it are placed on a different footing, as parts of a general scheme of reorganisation. This, should it ever be accomplished, as it doubtless will in time, will need careful inquiry respecting each institution which now has a separate and uncontrolled existence. All that appears to me to be necessary at present is to ascertain what may, after due consideration, be ultimately required, and what portions of it can be effected at once with as little interference as possible with the *status quo*. The problem has been partially solved as respects the poor by the Metropolitan Poor law Act of 1867 and the Medical Relief Disqualification Act of 1888. The extension of the principle of the latter to the Poor law infirmaries would at once provide all the in-door medical relief in acute disease needed for those temporarily disabled by sickness, that is required for London. In the voluntary hospitals and all dispensaries what is practicable at once without disturbing their autonomy is the introduction of a uniform system of record of their work, an independent audit of their accounts, and skilled inspection under the authority of a central board, which all are said to desire, but none appear ready to welcome. Once established on a satisfactory footing, if worked with care and discrimination, it would soon acquire such a knowledge of defects and imperfections as to lead to their correction without any violent interference with vested rights and cherished sentiments.

Want of cooperation.—The absence of cooperation between the general hospitals, the dispensaries, the Poor law infirmaries and the private practitioners affected by them was so well apprehended and stated by the Committee that I here reproduce their remarks in their own words.

"So far from there being at the present time any general system of combination or any definite division of work amongst the various institutions, they are, on the contrary, for the most part competing with one another at every point for public support and to a great extent for patients. This condition of things is shown to be wasteful as regards subscriptions of the public, and prejudicial not only to the public who subscribe their money, and to the sick, for whom the institutions exist, but also to the interest of medical science and education, since a wide field for observation and practice is closed to the clinical teacher and his pupils, whilst the hospitals for the sake of their schools, lest the requisite material should fail, are driven to take in and treat a crowd of patients unsuitable for hospital treatment, and the general practitioner complains that he is being 'ruined.' The above are the evils of the present system, or want of system, but little has been done heretofore to cure, to remedy or remove them. A few feeble attempts were

made in the direction of combined action, but they all failed, as might be expected, since isolated efforts would be of no value in such a matter. The true method of dealing with it was formulated by Sir T. Fowell Buxton in 1878, who wrote in a remarkable letter to *The Times* as follows—

"From a long acquaintance with hospital management I am convinced that its principal defects both in London and the country arise from want of organisation and cooperation and from the absence of all central control and of Government inspection. If the hospital system were complete, each central hospital would be surrounded by its satellites of dispensaries, cottage hospitals, special hospitals, convalescent hospitals, convalescent homes &c., which would intercept numberless cases which otherwise burden the wards of the hospital, and would furnish advanced education for the pupils of its school. Without some such authority as is possessed by School Boards it is impossible to organise such a body as this or to promote the scientific training of nurses. I do not believe that hospitals, upon which the demands increase year by year, can much longer keep pace with the requirements of modern medical practice or the precarious support of voluntary contributions, and I earnestly hope that Parliament will take the matter in hand before it is forced upon its notice by the collapse of some important institutions." No cooperation of any kind can be expected in existing circumstances or by voluntary efforts. The authority of the State, therefore, is necessary to inaugurate such a movement, and however unacceptable it may be in the first instance, it will soon be perceived that it was required in the public interests.

To what extent, then, should the State interfere in the matter without detriment to the autonomy of any of the voluntary hospitals or dispensaries? It should, I am of opinion, neither possess nor exercise any power of direct interference with local action, all control and immediate management being placed entirely in the hands of those in whom the direction of the institution is placed, either by selection, election, or any other manner in which these appointments are at present made. But it should, I submit, both possess and exercise authority to cause all such institutions to be inspected periodically by some independent agency to see that all rules and regulations for their management are carefully observed, that their books and records are properly kept, that proper facilities for admission and treatment are afforded, and that the funds from whatever source obtained are not wasted by needless extravagance, either for building or management, or in the maintenance of the schools attached to some of the hospitals, which latter should all be self-supporting. The inspector should invariably be accompanied by the resident controlling authority of the institution, to explain all matters that may need explanation and to afford any information the inspector may deem it necessary to call for. There should be nothing inquisitorial or calculated to interfere with local action or diminish personal responsibility in this inspection, the result of which should be duly reported to whatever central body may be created and appointed hereafter for consideration and action when any action may be required—such action being assigned with their consent to the authorities of the hospital concerned. At one of the conferences held in London the voluntary hospitals were defined to be "private associations performing public duties," and this being admitted, a public duty involves a public responsibility for its due and proper performance. This is a principle applied to many institutions of a more strictly private character than voluntary hospitals, such as lunatic asylums, mines, factories, *et ad genus omne*, and in none is it more imperatively needed than in our voluntary hospitals, for in the general hospitals of that class are contained the most helpless of all classes of the poor—the sick poor. They assuredly ought not to be left to the instability of precarious and uncertain charity, of which the plaintive and pitiful cry of "funds urgently required and beds unoccupied for want of funds" is constantly heard, proving how great are the present pressure and breakdown.

The moderate amount of public control suggested will probably be met with the customary contention of its checking the free exercise of the judgment of the practitioner in the treatment of disease, of diminishing his personal responsibility in the momentous issues of life and death, and of interfering with that liberty of action which induces us to tolerate all sorts of abuses many of them the outcome of the perverted sentimentality which is one of the most regrettable reproaches of the present time. The most serious obstacles will be the belief that when the State steps in to supervise the

Mystery hangs over the cholera at Marseilles. A great deal of unnecessary word fencing is indulged in that may mislead the casual inquirer, but which, as far as I have been able to judge, tends rather to exaggerate than to mitigate the evil. If anyone speaks of cholera he is authoritatively told at the Mairie as at the Préfecture, that there is no cholera epidemic. Then insinuations sometimes not altogether pleasant, are made that the cholera

their night-soil out into the street or on to the nearest heap of rubbish. Thus the dejections of a visitor from Paris, or some other infected locality, suffering from a mild attack of cholera might very easily have been mixed with the sand and earth of the street, where the children play about. If the soil of the streets was contaminated it was natural that the children playing and rolling about in the streets should be the first victims. The total absence of sewers, the frequent influx of visitors when cholera prevailed in so many parts of France, the throwing out of dejecta into the streets that constitute the playground of children, these facts alone suffice to account for the outbreak of cholera.

The epidemic having once begun, its rapid spread and disastrous effects can with equal facility be explained. First, there was the usual attempt at concealment, then a most determined resistance to all prophylactic measures. There are also a great number of very poor and intemperate people, and of course they were the principal sufferers. Yet some of the cleaner and wealthier sections of the population likewise suffered. One rather interesting case is that of a woman aged thirty-eight years and her child aged five years. Both died from cholera. The woman was strong, very clean and healthy, and lived in a good, well kept house. This woman was, however, a thorough miser, and though possessing ample means could never be induced to spend sufficient money on the purchase of food. Then there is the case of a very healthy, robust man aged forty-two. At two o'clock one afternoon he helped to carry a body and bury a woman who had died from cholera, at eight o'clock the next evening he himself died from the same disease. The linen of a woman who had died from cholera was washed on a Sunday morning at eight o'clock by a woman aged twenty-two years, of robust health, and whom the mayor described to me as being "built like a wall." In the afternoon this woman was seized with violent vomiting and she died on the day following at 4 p.m. The linen she washed had not been disinfected, the apparatus for disinfection had not yet been sent to Portel.

When it became known that cholera had broken out at Portel, the Minister of the Interior gave orders that a portable stove for disinfection by steam superheated under pressure should at once be sent to that place, and as there is no hospital available in the district a Tollet ambulance tent was also lent by the Government. These tents, resting on Gothic shaped iron arches, make very strong portable hospitals that will resist the wind even when blowing very strongly. Instead, however, of considering themselves fortunate in the possession of an isolation hospital, the inhabitants of Portel gathered in force and threatened to destroy the ambulance. Gendarmes had to be employed to protect the men who were engaged in putting up the field hospital. When this work was accomplished not one of the numerous patients would consent to allow himself to be taken to the hospital thus provided. As the mayor would not assume the responsibility of ordering the forcible removal of the patients the tent was of no use whatever, and it was subsequently removed to the neighbouring village of St Etienne. Cholera had reached this village, and its inhabitants, less superstitious, less ignorant and prejudiced than the fishermen of Portel, gladly waived themselves of the tent hospital, and it there proved of great use in preventing the spread of the disease.

The Commission of Hygiene of the Boulogne arrondissement met and urged that all the wells at Portel should be closed. These are mere surface wells and are all exposed to contamination. The municipality of Boulogne offered to supply water to Portel gratuitously if the municipality of the place would go to the expense of sending horses to fetch the water carts from Boulogne, but the people of Portel would not listen to this offer. They strongly objected to incurring any expense and, above all, would not allow their wells to be closed. The sub-prefect, with the "doctor for epidemics," and a posse of gendarmes to protect them, went to Portel and forcibly carried away the piston rods of the pumps connected with the wells that were most likely to be contaminated, but two or three days afterwards the people removed the stones covering the wells and, with ropes and buckets, got water out of them. So little was the danger of drinking well water understood that the mayor of Portel was about to issue a proclamation to his electors explaining that he was not responsible for the closing of the wells. Fortunately the sub-prefect heard of this in time to explain to the mayor that it was his duty to strengthen the moral

authority of the Government and not to appear as if he disapproved of what had been done. Notwithstanding the resistance and ill will of the inhabitants of Portel, a great deal was done on their behalf, and the mayor expressed to me personally the gratitude he felt, and was anxious that public attention should be called to the devotion shown by outsiders. Thus Dr Orion, "doctor for epidemics," came repeatedly from Boulogne and went bravely into the foulest dens to attend the sick. Dr Houzel also came from Boulogne, and both these gentlemen worked very hard and gratuitously. The Minister of the Interior despatched Dr Pierre Aymard and Dr Girocle, and two Sisters of the Bon Secours Order were also sent. Day and night the Sisters nursed the sick in their dirty, ill ventilated cottages, exposing themselves to every risk of contagion and showing the greatest self denial. Sulphate of copper in large quantities was distributed gratuitously, and many things—furniture, bedding &c.—likely to be contaminated were burnt. The rooms were disinfected by being stripped of their paper and, when quite bare, were washed with mercurial and carbolic acid solutions, yet in one particular house cholera broke out three different times, though on each occasion the premises had been very carefully disinfected. This seems to be exceptional. I had not before heard complaints of cholera breaking out again in a house that had been carefully disinfected, but the whole village was so thoroughly infected that it is easy to conceive how the specific germs might be carried again and again into a house, however carefully it might have been cleaned.

Of course, I made a point of visiting some of the houses where the greatest number of cases of cholera had occurred. Thus, in the Rue Victor Hugo I entered a house where a good many had occurred. In spite of all the disinfecting and all the cleaning I found the backyard of this cottage flooded with water in which rubbish and faecal matter were floating. There was no closet, no pail, no sanitary convenience whatever. The paper on the wall of the sitting room had dropped off in consequence of the damp, due, in a measure, to the chronic flooding of the back yard. In the Rue du Puits I came upon one of the principal wells of the town. There was a pump, and immediately below the pump was a square stone with a circular one fitted in the centre. A hole in the middle of the latter enabled a hook or the fingers to be inserted. The stone could thus be raised and direct access obtained to the water beneath. At the same time, through this same hole, dust, mud and water from the street could drop into the drinking water below, but, worse than this, people came with dirty utensils, pails and so forth, and washed and rinsed them out upon the stone with the water from the pump. It will be easily understood that the well water would thus be contaminated, and in a most dangerous and filthy manner, thus armed force had to be employed to prevent people drinking this water. In another very wretched house I found a mother with twin children, who were literally dying from starvation. The father had been carried away by cholera, leaving a widow and four children. The five slept and lived together in one very small damp room. A drain from the back yard to the gutter in front passed under this room and was very offensive. A little further on I found a row of houses built on a level, though the street rose, the houses at one end of the row were consequently some four or five feet below the street. A space in front of these houses had been made to give access to the doors, but, being below the level of the street, this sort of front yard or area could not be drained and there was a pool of green, stagnant, foul water. In a court a house was shown to me where two deaths had occurred, a wall in front of the dwelling room blocked out the light, and in the passage leading to the dwelling there were water offal and faecal matter which befouled the atmosphere. In another house near the beach, which used to be a *café*, there had been four cases and three deaths. The place was gloomy, with a stifling atmosphere, and this in spite of recent disinfection. Finally, I entered a cellar dwelling. It seemed more like a cave than a cellar. A wretched man, his wife and several children lived in this hole. The few sticks of furniture stood on the bare earth, as also did their bed, which was placed in a distant dark corner. It was only the front part of this cave that received a little light and air from the street. For this wretched home these people paid only 2s. 10d. per month. This is a small enough sum, and they certainly could not expect good accommodation for such a price, but the question is whether people who cannot afford for a whole

family more than about 3s a month for rent ought to be allowed to live anywhere outside asylums, poor houses, work-houses, or such institutions. Landlords should be compelled to provide wholesome tenements, but tenants should be able to pay a reasonable rent. Till this condition is attained there never will be perfect sanitation.

It is difficult to say how many cases of cholera there were at Portel, as so many persons concealed the fact of their being ill. However 130 cases are known to have occurred and there were 76 deaths. Considering that the population of Portel only numbers 5329 according to the last census, it will be seen that the epidemic was severe. The average

MARSEILLES

The Cholera in October, 1892—The Cholera in February, 1893—Remarkable Contrast between the Two Epidemics

Mystery hangs over the cholera at Marseilles. A great deal of unnecessary word fencing is indulged in that may mislead the casual inquirer, but which, as far as I have been able to judge, tends rather to exaggerate than to mitigate the evil. If anyone speaks of cholera he is authoritatively told at the Municipalité, as at the Préfecture, that there is no cholera epidemic. Then insinuations, sometimes not altogether pleasant, are made that the cholera

number of deaths for the last ten years at Portel was 103 per annum. Dr Armand, the Government delegate, the mayor assured me had made this calculation and it would equal a death rate of 20.2 per 1000 per annum, but the death rate from cholera alone during the recent epidemic amounted to 14.25 per 1000 of the population. The Portel epidemic may therefore be considered as one of the most severe that occurred in France during the course of last year. Doubtless it would have been even more severe but for the fact that energetic disinfection was enforced and that the town is exposed to the purifying and health imparting sea breeze.

has been invented by foreigners anxious to promote the commercial interests of other nations to the detriment of the port of Marseilles. Yet it is now freely admitted that there was cholera at Marseilles last October, but great efforts are made to conceal the fact that there has been cholera at Marseilles during the month of February this year. Because the number of deaths has not been considerable, therefore the existence of an epidemic is denied. Then there is the practice of qualifying deaths as "suspect." There are however a few hygienists at Marseilles who care more for saving human life than for playing with words in the hope that foreign Governments will not take measures against ships.

coming from Marseilles. I was therefore able to obtain the accompanying diagrams. The first represents by squares the number of deaths occurring each day during the months of September, October and November last year. The figures possessed at the Ministry of the Interior in Paris show that there were four deaths in September, eighty two in October and four in November, and there is scarcely any difference between these figures and those of the diagram. Whilst these cases of cholera occurred in October there was a decrease in the general mortality. Most of the victims lived in the lower part of the town, especially in the narrow streets by the old port, which had suffered so much during the great epidemics of 1884 and 1885. The epidemic was spread over a period of fifty to sixty days, and on Oct 1st there was a great storm, which in part flooded the lower portion of the town. This year, on the contrary, the weather has been exceptionally dry. The rain fall for January was only 16 millimetres, or a third of the normal rainfall. In 1892 there fell 52 millimetres of rain in the same month. The epidemic commenced on Feb 2nd and seems to have ceased on Feb 15th. On Feb 21st there had been another death, about which doubts were entertained. In any case, the epidemic of February has proved to be a little more severe than that of October last, for I am informed, on the best authority that there have been 102 deaths. The accompanying diagram does not quite correspond with these figures, but it does correspond with the figures given by the Prefecture to the foreign consulates. In the latter case the distribution by date is different, though the total is the same. From this I may conclude that there have been from Feb 2nd to Feb 22nd 102 deaths from cholera, of which 87 deaths are officially recognised as such. As differing still further from the epidemic of October last, the accompanying diagram shows that the general mortality was much higher than usual. As a rule, there die close upon thirty persons per day in Marseilles but the number of deaths during the first fortnight in February was much greater and this would still be the case even if one were to deduct the deaths from cholera. Finally, the February epidemic was spread over a vast area, principally on the outskirts of the town and on comparatively elevated ground. It seems, therefore, to have been in many important respects very different from the epidemic of October, and both the epidemics of October, 1892, and February, 1893, differ very considerably from the great epidemics of 1884 and 1885. This latter circumstance gives rise to the hope that there will be no serious epidemic this year. Dr Mirrer, who is one of the leading authorities on this question and has very elaborately studied the previous epidemics, urged, when discussing the matter with me, that cholera at Marseilles always begins with a few isolated cases and then suddenly develops, a large number of deaths taking place daily. This was not the case either in October or in February, and therefore he hopes that Marseilles is not at the present time especially susceptible to cholera, otherwise, why should the epidemic have stopped so soon and caused so little damage? It is ardently to be desired that this somewhat sanguine view of the situation may be verified by the course of future events, but the summer is coming and Marseilles is abominably dirty

INTESTINAL PARASITES BELONGING TO THE CLASS NEMATODA

THREE lectures on this subject were delivered at the Royal College of Surgeons on Feb 20th, 22nd and 24th, by Dr H J Campbell, Senior Demonstrator of Biology at Guy's Hospital. He gave a short historic account of the views concerning intestinal parasites, which was followed by a brief description of the general anatomy of the nematodes. A general review of the life histories of the parasitic species was then given. First, those forms which are only occasionally parasitic, being free living animals for the greater part of their lives, were mentioned, after which came a description of those species which pass their larval stages in damp earth or water, but which must gain admittance to the intestine of an animal before they can grow up into sexually mature adults. Next those forms were described which are obliged to pass their larval condition in the bodies of intermediate hosts in order to reach the stage of development which is neces-

sary if they are to grow up into adults in the intestine of their final hosts. Fourthly, mention was made of some species which show an alteration of generations, as a rule, in these cases, the intestinal parasite produces by parthenogenesis young animals which grow up outside the body of the host into sexually mature adults, these, in their turn, give rise to embryos which, after they have been swallowed by their host, develop into another asexual generation. Finally came the species which pass the whole of their lives inside the bodies of their hosts, and which in consequence neither require any intermediate host for their development nor are free living for any portion of their lives, but whose eggs are able to develop into mature adults in the bodies of their hosts, even if they are swallowed immediately after they have been passed.

The second lecture commenced with a description of the *ascaris lumbricoides*, the experiments of Grassi and Lutz, by means of which it was conclusively proved that no intermediate host is necessary for the development of this parasite, being described at some length. It appears, from the results obtained by Lutz, that it is necessary for the eggs to be still covered with their albuminous coatings when swallowed by the host if they are to grow up into adults in his intestine. The symptoms said to have been caused by the presence of *ascarides* in the intestine were mentioned, but it was shown that, although these parasites may undoubtedly in rare cases cause obstruction, yet, as a rule, hardly any or no symptoms are produced by them. Apparently, the most usual vehicle of infection is drinking water. Occasionally, however, food may become contaminated if the hands are soiled with mud or earth containing the eggs. This view is supported by the facts that *ascarides* occur most frequently during rainy seasons, and also that they are most prevalent in persons living on the borders of lakes and in swampy districts. Further, cases have frequently occurred in which direct infection through polluted drinking water has been shown to be exceedingly probable, if not quite certain. The *ascaris lumbricoides* usually inhabits the small intestine of man, but it has, however, been also found in the bile ducts and after perforation of the intestine in the peritoneal cavity &c. The *ascaris mystax* of the cat and dog very much resembles the *ascaris lumbricoides* both in appearance and life history. It is, however, somewhat smaller and, in addition, possesses characteristic wing like appendages to its head. The eggs of both species are exceedingly resistant both to cold and dryness, and can retain their vitality for long periods, being able to develop, when suitable conditions are provided for their growth, even if several years have elapsed since they were laid. That the life history of the *ascaris mystax* is similar to that of the *ascaris lumbricoides* has been proved by Grassi by means of feeding experiments upon dogs. The *ascaris megalocephala* is the largest of the *ascarides*, it has never been found in man, but it is exceedingly common in the horse. Here, again, no intermediate host is necessary and the vehicle of infection seems, in the majority of cases to be drinking water. The *trichocephalus dispar*, or whip worm, which inhabits the cæcum and small intestine of man, is about two inches in length, the males are smaller than the females, and, like those of most parasitic nematodes have bent-up tails which are provided with spicula. This parasite has been credited—though on very insufficient grounds—with being the cause of *beri beri*. There seems no doubt, however, that when present in large numbers it may give rise to intestinal catarrh. The anatomy and life history of the *oxyuris vermicularis*, or thread worm, were next described. Here, again, it has been proved by feeding experiments made in this case by Cobb that no intermediate host is necessary for the development of this worm, the eggs being able to develop into mature adults in the intestine of the host if they are swallowed immediately after they have been laid. The natural habitat of this parasite is the cæcum or the lower part of the ileum.

The third lecture was devoted to the consideration of those species which produce grave diseases in their hosts. The most important of these the *necylostomum duodenale*, was first described as to its anatomy and life history. Although no intermediate host is necessary, the eggs are unable to develop into adults in the intestine if they are swallowed immediately after they have been laid. It is necessary for them to first develop in muddy water or upon damp earth into rhabditiform larvae, which, after moulting two or three times at last reach a stage in which development is no longer possible until they have entered the intestine of man. More

over the eggs die if the temperature of the water or earth is too low, and this accounts for the fact that, although occasional cases of ancylostomiasis have been observed in Northern Europe, the disease has never been endemic, except in warm climates. The symptoms of the disease were next entered into and a historical account given of it. The connexion of the parasite with the disease, which had been variously described as "mal d'estomac," "cachexie aqueuse," "tropical or Egyptian chlorosis," "mal de cœur" &c., was first discovered by Griesinger in 1854. Numerous observers have recorded the frequency with which the ancylostomum duodenale has been found in cases of beri beri, and, although it seems certain that the parasite is not the cause of the disease, yet there is very little doubt but that it plays a very considerable part in producing the anemia so frequently present. The *doctimus trigenocephalus* of the dog, the *strongylus contortus* of the sheep and the *strongylus convolutus* of the ox all produce in their respective hosts diseases very similar in the symptoms and results to that produced in man by the ancylostomum duodenale. The life history of the *strongylus armatus* of the horse is peculiar in some respects. The adult condition is passed in the large intestine of the host, the eggs being evacuated with the faeces. As with the ancylostomum duodenale, the larval stage is passed in water or in damp earth, after which development takes place, not in the intestine of their host, but in the mesenteric arteries. Apparently the larvæ, immediately on reaching the intestine, commence to bore through its walls and to make their way into the mesenteric arteries, where they give rise to aneurysmal dilatations, in which the larvæ remain for some little time. It seems, however, that they never grow up into adults in these vessels, but make their way by some means or other into the large intestine of their host, where they become sexually mature. The *heterakis maculosa* is a parasite which inhabits the intestine of the pigeon, producing frequently a fatal disease in its host. Unterberger has shown that the eggs of this nematode require to be kept for about seventeen days under suitable conditions outside the body of the host before they reach the stage at which development in his intestine is possible. If they are ingested earlier they produce no effect. If, however, the necessary interval has been allowed to elapse ova commence to appear in the faeces about three weeks after infection has taken place. The experiments made by Grassi on the *spiroptera sanguinolenta*, which inhabits the alimentary canal of the dog were next described. These experiments show that for this parasite an intermediate host is necessary, which in this case is the Eastern cockroach. Apparently dogs become infected by eating this insect. The life history of the *rhabdomena strongyloides* (*anguillula intestinalis anguillula stercoralis*) is a peculiar one. The *anguillula intestinalis* lives in the intestine of man and gives rise, probably by parthenogenesis, to ova, which develop into sexual animals. These were for a long time considered to form a separate species, being known as the "*anguillula stercoralis*," but it has been shown that if the embryos produced by them are swallowed by man they grow up into the asexual intestinal form. Thus here we have an alternation of generations—sexual and asexual. The evidence for and against the view that Cochlin China diarrhoea is caused by the presence of this parasite was entered into and the conclusion arrived at was that, although this worm may undoubtedly give rise to enteritis, yet it cannot be considered to have any causal relation to the disease first mentioned. The lectures were closed by a summary of the anatomy and life history of the trichina spiralis and the effects produced by it upon its host.

THE ARMY ESTIMATES FOR 1893-94

THE Army Estimates form a voluminous and somewhat intricate, but nevertheless clear and admirably arranged Parliamentary paper embodying statements of the variations of the numbers of Her Majesty's British forces, explanations of the increases and decreases in the estimates the amounts allocated for the colonies and Egypt, and the amounts provided for each arm of the service and for various miscellaneous establishments. The amount for total effective and non-effective services is £17,431,293, and the net increase for the year is set down at £171,600, but, as will be seen, the increase has not been caused by the medical services and establishments, for, according to the preliminary statement

explanatory of the differences in the amounts proposed for 1893-94 and the amounts voted in 1892-93, Vote 4 (Medical Establishment) shows a decrease of £1900 for this year. This decrease is attributable to the pay of the medical staff having been overestimated in past years, insufficient allowance having been made for casualties. The estimates of the sum required to defray the expense of the pay &c. of the medical establishment and cost of medicines is put down at £288,200 and, amongst the subheads under which this vote is accounted for, we may mention the pay of the medical staff, which is estimated at £225,800 for 1893-94, as against £228,000 in 1892-93, showing a decrease of £2200. The estimated pay of militia surgeons and civilian medical practitioners &c. amounts to £9950, showing an increase of £400 on that of last year. The cost of medicines &c. remains the same—viz., £18,000. The total strength of the medical staff, including that on the Indian Establishment, amounts to 954, from which 335 have to be deducted for India. The number of men on the regimental establishments of the army and auxiliary forces and of the reserves is estimated at a total of 712,507. The number of men of British regiments of all ranks serving in India is 72,858. A statement showing the rates of pay and the allotment of the staff &c. to the various districts and stations at home and abroad is given in Appendix No. 8, page 168 *et seq.*; and the total emoluments of officers serving at home are shown in Appendix No. 19 p. 217. Vote 11, subhead 1, for the staff of the Army Medical School, Netley, amounts to £7023, which is a slight decrease on the preceding year. Vote 13, Subhead A, provides for the Director-General and medical officers at headquarters at an estimated cost of £4850. In our examination of these estimates, we have not so far been able to ascertain any evidence of the War Minister's intentions in regard to the recommendations made in the report of Lord Wantage's Committee.

ALABASTER AND OTHERS v THE MEDICAL BATTERY COMPANY

THIS was an action brought by the proprietors of the *Electrical Review* to recover damages for a libel contained in a circular issued by the defendants. The circular was issued in the following circumstances. The *Electrical Review* addressed a series of articles to the subject of the *Harness* "electro-pathic belt," in which the worthlessness of these contrivances for curative purposes was exposed, and one article in particular commented upon an action brought by the defendant company in the Bloomsbury County Court for the recovery of the price of one of these belts. In the course of that article the following observations occurred—"It is quite impossible for the belt to generate any current as worn upon the body for the external circuit was not completed by the connecting up of the zinc and copper poles, nor were any means indicated to the defendant of doing so for himself. Assume that one of these belts is properly connected up and that the exudations of the body act upon the metals so as to produce, by chemical action, an insignificant amount of electrical energy does the current so produced pass through the body, and is it of any use medically? We reply emphatically 'No.' If the much-to-be-pitied persons of both sexes who so readily fall into the snare set by the president of the British Association of Medical Electricians and of the Medical Battery Company would only reason with themselves a few minutes reflection ought to convince the most foolish that the idea of a poor debilitated body generating the electricity for alleviating its own sufferings is most preposterous. But what words can be found sufficiently strong to condemn the practice carried on in the Oxford street mansion in the treatment of rupture? That it should be possible in these days of enlightenment and in the midst of the largest city in the world for 16,900 cases of a serious malady to have been treated by a man having such qualifications for the task as the consulting officer of the Medical Battery Company proved himself in the witness box to possess is beyond the comprehension of any reasonable being and if ever there was a matter demanding the immediate attention of the Public Prosecutor the revelations made at the Bloomsbury County Court point to it. If the treatment by an unqualified man of incurable disorders which require careful and skilful medical attention is not

actionable at law, the sooner some Bill is passed to make it so the better for suffering humanity. We trust that the report of this disgraceful case may be disseminated far and wide, for it will do much to enlighten the public as to the real status of Mr O B Harness. No wonder that he can spend yearly on advertisements a sum which most people would consider a princely fortune if 16,900 cases are treated at five guineas a time—probably more in numerous cases—in between six and seven years."

Upon the publication of this article the solicitors of the Medical Battery Company issued the circular complained of in the present action to some 500 newsagents of the metropolis, warning them that the *Electrical Review* and *Science* *Siftings* contained "malicious libels" upon the defendant company, and that if these or any future publications containing defamatory articles or paragraphs were sold or circulated by the persons addressed, the company would hold them responsible. The natural effect of this circular was to deter the newsagents from selling the papers in question. Evidence upon this head having been given, the plaintiffs proposed to call evidence in justification of the articles which they had written. To this evidence objection was taken in behalf of the defendants that the merits of the Harness belts did not come into question in the present action, the plea upon which they relied being that the circular was issued *bona fide* and in self defence and therefore upon a privileged occasion. The Lord Chief Justice, however, held that the proposed evidence was material upon the issue as to the defendants' *bona fides* in issuing the circular. Thereupon Sir Edward Clarke, in behalf of the defendants, elected to admit that the circular was a libel and to leave the question of damages to the jury, stating that his clients were not prepared in this action to go into the question of the merits of the belt. The matter was accordingly left to the jury upon that footing, and they awarded to the plaintiffs damages to the amount of £1000. Judgment for that amount and for costs was given and the Lord Chief Justice refused a stay of execution.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT

REPORTS OF MEDICAL OFFICERS OF HEALTH

Isolation Accommodation and Notification in the County of Surrey—Dr Seaton has made a most valuable report to the Sanitary Committee of the County Council upon these subjects. Referring first to the question of notification, we are told that all the sanitary authorities in the county, with one exception, have now adopted the Notification Act, the authority which still persistently refuses to adopt it being the Godstone rural. Both Dr Seaton and Dr Oldman have done their best to persuade the authority to complete the county list, but, so far, in vain. Amongst the Surrey united rural districts Dorking stands alone in being without any hospital provision, and it is of some interest to note that in this district the prevalence of scarlet fever has been much greater than in the two adjoining ones of Guildford and Reigate. It is also to be noted that the proportion of persons attacked to houses invaded was likewise greater in the Dorking district. These statements presumably refer to the year 1891. Negotiations have taken place between the sanitary authorities comprised within the Epsom union with a view to united action in providing a fever hospital. The Epsom urban authority have, however, refused to join, and are proceeding to erect a hospital of their own. At the present time about one-third of the population of the county is said to be provided with isolation accommodation, a fact which shows considerable advance on the condition of things existing eighteen months ago. Dr Seaton is evidently an advocate of further powers being conferred upon the county council as regards hospital provision. Referring to the character of isolation accommodation, he remarks "I cannot too strongly comment upon the undesirability of establishing even as temporary accommodation, hospital provision likely to bring discredit upon the system of notification and isolation of infectious diseases." We are in entire accord with these sentiments, and naturally also agree with Dr Seaton when he urges that persons admitted into a fever hospital suffering from one complaint should not be exposed to the risk of contracting another. Although it is possible,

in a very large degree, to prevent this occurrence, we fear that in some cases at least, whatever precautions be adopted, some risk must be run—as, for instance, when patients are admitted into the wards of a fever hospital—of incubating some other disease in addition to the one from which they are suffering. This, we are afraid, must always be one of the necessary drawbacks of a fever hospital, or, in fact, of any hospital system whatever. No justification, however, can be found for a sanitary authority which allows small pox to be treated in the same hospital with other infectious diseases.

Chelmsford Rural District—After dealing with the population, area and geographical and physical conditions of the district, Dr Thresh gives qualitative analyses of samples of water taken from various villages, he then discusses the questions of sewerage, excrement and refuse disposal &c. The same difficulty in connexion with the housing of the working classes seems to obtain here as elsewhere, and Dr Thresh states that before advising his authority to take advantage of the powers conferred upon them by Part III of the Housing of the Working Classes Act he is watching with interest the experiment in that direction at Ixworth, where a number of cottages are about to be erected by the Thingoe rural sanitary authority. Whilst upon the subject of burial grounds Dr Thresh seems to favour the view that the county councils should be empowered to erect crematoria at convenient spots in their counties. In drawing up a set of by laws for the district, we are glad to see, advantage has been taken of the powers conferred by the Public Health Acts Amendment Act of 1890. During the year 1892 several minor improvements have been effected, and it has been decided to provide isolation accommodation for the district, a system of sewers for one village and a public water supply for several others. We agree with Dr Thresh that it is much to be regretted that the Chelmsford urban sanitary authority could not see their way to join with the rural authority in the erection of a fever hospital. The past year has been fruitful in epidemics, and influenza, measles, diphtheria, mumps, German measles and scarlet fever have each claimed their victims in the district. The zymotic death rate was 1.83. We notice with regard to German measles that here, as in other places, there seems to have been some difference of opinion as to the nature of the complaint. No less than 97 cases of diphtheria, concerning which a special report has been issued, occurred during the year, and they yielded a case mortality of 11 per cent. Last year, with fewer cases, the mortality was 20 per cent. Several cases of diphtheria seem to have been closely associated with attacks of scarlet fever. There can, as Dr Thresh states, be little doubt that the condition of throat produced both by scarlet fever and measles forms a very suitable nidus for the activity of the bacillus of diphtheria. The general death rate in the district was 18.2 as against 15.4, the mean of the preceding twelve years. The excess has fallen entirely upon the aged and is no doubt due in large part to the number of deaths (47) which were attributed to the effects of influenza. As Dr Thresh remarks, it is to be hoped that the virulence of this disease is not capable of further intensification. This report is one of much interest and we hope it will be widely read.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

In thirty three of the largest English towns 6783 births and 4125 deaths were registered during the week ending March 4th. The annual rate of mortality in these towns, which had been 19.2 and 19.7 per 1000 in the preceding two weeks, further rose to 20.8 last week. In London the rate was 20.8 per 1000, and almost corresponded with the mean rate in the thirty two provincial towns, which was 20.9 per 1000. The lowest rates in these towns were 12.7 in Leicester, 15.3 in Croydon, 15.4 in Nottingham and 16.3 in West Ham, the highest rates were 24.7 in Leeds, 24.9 in Bolton, 25.6 in Manchester, 27.0 in Plymouth and 29.5 in Norwich. The 4125 deaths included 398 which resulted from the principal zymotic diseases, against 368 and 386 in the preceding two weeks, of these, 102 were referred to whooping cough, 98 to measles, 61 to diphtheria, 49 to diarrhoea, 44 to scarlet fever, 32 to "fever" (principally enteric) and 12 to small pox. No fatal case of any of these diseases occurred last week in Swansea or in Wolverhampton, in the other towns they caused the lowest death rates in Leicester, West Ham, Gateshead and Oldham, and the highest rates in Manchester, Halifax, Plymouth,

Cardiff and Bolton. The greatest mortality from measles occurred in Portsmouth, Derby, Plymouth, Preston, Leeds and Bolton, from whooping cough in Cardiff, Halifax, Burnley, Brighton, Nottingham, Norwich and Salford. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 61 deaths from diphtheria included 37 in London, 4 in Manchester, 3 in Liverpool and 3 in Cardiff. Five fatal cases of small pox were registered in London, 2 in Manchester, and 1 each in Liverpool, Nottingham, Salford, Halifax and Hull, 183 cases of this disease were under treatment in the Metropolitan Asylum Hospitals and 15 in the Highgate Small pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2210, against 2513, 2402, and 2293 on the preceding three Saturdays, 203 new cases were admitted during the week, against 217 and 178 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 350 and 427 in the preceding two weeks, declined again to 385 last week, and were 111 below the corrected average. The causes of 87, or 2.1 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Croydon, Cardiff, Leicester, Sunderland, and in five other smaller towns, the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Salford and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the preceding three weeks from 24.2 to 20.4 per 1000 rose again to 23.2 during the week ending March 4th, and exceeded by 2.4 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 15.7 in Aberdeen and 16.8 in Leith to 29.2 in Perth and 33.8 in Dundee. The 654 deaths in these towns included 53 which were referred to measles, 15 to whooping cough, 9 to diphtheria, 8 to diarrhoea, 3 to scarlet fever, 2 to "fever" and 1 to small pox. In all, 91 deaths resulted from these principal zymotic diseases, against 109 and 89 in the preceding two weeks. These 91 deaths were equal to an annual rate of 3.2 per 1000, which exceeded by 1.2 the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 57 and 42 in the preceding two weeks, rose again to 53 last week, of which 24 occurred in Dundee, 15 in Glasgow and 6 in Paisley. The 15 deaths referred to whooping cough showed a further decline from those recorded in recent weeks, and included 13 in Glasgow and 2 in Paisley. The fatal cases of diphtheria, which had been 8 and 10 in the preceding two weeks, were 9 last week, of which 7 occurred in Glasgow. The deaths from scarlet fever, which had been 8 and 10 in the previous two weeks declined to 3 last week, and included 2 in Glasgow, where the fatal case of small pox was also recorded. The deaths referred to diseases of the respiratory organs in these towns, which had declined from 182 to 135 in the preceding three weeks, rose again last week to 171, and exceeded by 16 the number in the corresponding week of last year. The causes of 62, or more than 9 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin, which had been 29.7 and 27.4 per 1000 in the preceding two weeks, rose again to 27.7 during the week ending March 4th. During the first nine weeks of the current quarter the death rate in the city averaged 28.9 per 1000 against 22.9 in London and 22.2 in Edinburgh. The 186 deaths in Dublin during the week under notice showed an increase of 2 upon the number in the preceding week, and included 6 which were referred to "fever," 5 to whooping cough, 2 to diarrhoea, and not one either to small pox, measles, scarlet fever or diphtheria. In all 13 deaths resulted from these principal zymotic diseases equal to an annual rate of 1.9 per 1000 the zymotic death-rate during the same period being 1.8 in London and 1.0 in Edinburgh. The deaths referred to different forms of "fever" which had been 7 and 2 in the preceding two weeks rose again to 6 last week. The fatal cases of whooping cough which had been 1 and 2 in the preceding two weeks further rose to 5

last week—a higher number than in any week since June, 1892. The 186 deaths registered in Dublin last week included 35 of infants under one year of age and 45 of persons aged upwards of sixty years, the deaths of infants showed a slight further increase upon recent weekly numbers, whilst those of elderly persons showed a further decline. Six inquest cases and 5 deaths from violence were registered, and 67, or more than a third, of the deaths occurred in public institutions. The causes of 21, or more than 11 per cent., of the deaths in the city last week were not certified.

THE SERVICES

MOVEMENTS IN THE MEDICAL STAFF

SURGEON CAPTAIN WM WILFRID WEBB, M.B., Bengal Army, T.H.P., took over charge of his appointment as Secretary to the Army Medical School, Netley, and curator of the museum on March 1st. Surgeon Captain A. E. Morris is posted to the Medical Division of the Royal Victoria Hospital, Netley, on return from leave of absence. Brigade Surgeon Lieutenant-Colonel W. J. Martin, A.M.S., having embarked at Portsmouth for India on the 2nd inst., is struck off the strength accordingly. Brigade Surgeon Lieutenant Colonel Thomas O'Dwyer has been appointed Principal Medical Officer of the South Eastern District. Brigade Surgeon Lieutenant-Colonel Steele has been appointed to the Charge of the Station Hospital, Western Heights, Dover. The following officers have embarked in the *Malabar* for India—Surgeon Major Myles and Surgeon Captains Stalkart and Burchrell. Surgeon-Major Robbins has been appointed to Pembroke Dock. Surgeon Captain Hunter has arrived at Hong Kong and Surgeon Captain Hickman Morgan at Sierra Leone.

ARMY MEDICAL STAFF

Surgeon Colonel Thomas Rudd, M.D., to be Surgeon Major-General, vice S. A. Lithgow, M.D., C.B., D.S.O. retired, Brigade Surgeon Lieutenant-Colonel Thomas F. O'Dwyer, M.D., to be Surgeon Colonel vice T. Rudd, M.D., and Surgeon Lieutenant-Colonel Thomas O'Reilly to be Brigade-Surgeon Lieutenant-Colonel, vice T. F. O'Dwyer, M.D. (all dated Feb 6th, 1893).

INDIA AND THE INDIAN MEDICAL SERVICE.

The following admissions to the Indian Medical Service have been approved to be Surgeon Lieutenants (dated Jan 30th, 1893)—Bengal: Charles Milne, Vivian Godfrey, Drake Brockman, William Young, John Joseph Bourke, George Yeates Cobb Hunter, Bernard Robert Chatterton, Cedric Barkley Prall, Chas. Edward Williams, John Norman MacLeod, Walter Holland Ogilvie Thomas Alfred Ollivant Langston, Richard Heard, Edgar Rowe Parry, Walter Hood Orr, and Paxton St. Clair More. Madras: George Bidie and John Plowden Morton. Surgeon Captain G. A. T. Bray, doing duty, Belgaum and Bangalore Districts, is posted to do duty, Rangoon District. Surgeon Lieutenant-Colonel W. F. Murray is appointed to act as Civil Surgeon of Shahabad. Surgeon-Major Owen, C.I.E., C.M.G., of the Commander in Chief's Staff, will on the departure of Lord Roberts be appointed Chief Medical Officer of the Patiala State. Surgeon Captain J. Murry, Professor of Pathology and Materia Medica, Lahore Medical College, has obtained furlough to Europe on medical certificate for nine months. Surgeon Major A. W. F. Street, D.S.O., is allowed furlough for two years from April 18th, 1893. Surgeon Captain W. H. Burke, M.B., Assistant to the Civil Surgeon, Poona, is allowed privilege leave of absence for three months from March 2nd, 1893. Surgeon Major H. P. Jervis, I.M.S., has been granted extension of leave for six months. Surgeon Lieutenant-Colonel J. D. Gunning, A.M.S., has been granted leave for six months. Surgeon Captains F. H. Treherne, A.M.S., G. H. Frost, I.M.S., and Surgeon Lieutenant H. M. Earl, I.M.S., have passed the lower standard examination in Hindustani. Surgeon Colonel Carter, who, as Professor in the Lahore Medical College has done some excellent work in connexion with Indian native poisons, will retire from the service in April next.

NAVAL MEDICAL SERVICE.

The following appointments are announced—Staff Surgeons J. Acheson, M.D., to the *Brisk* on promotion; H. S. R. Sparrow to the *Rapid* on promotion, and A. Kidd to the *Cyclone* on promotion (all dated Feb 26th, 1893), J. H. Beattie to the *Royalist* (dated March 3rd, 1893). Surgeons

A. J. Pickethorn to the *Orlando* and E. A. Penfold to the *Goldfinch* (both dated March 3rd, 1893), J. R. McDonnell to the *Neptune* (dated March 1st, 1893), R. T. Bowie to the Chatham Hospital and G. G. Bishop to the *Iron Duke* (both dated March 3rd, 1893) Surgeon and Agent A. D. Vardon, at Pennant and Gardenstown (dated March 1st, 1893)

VOLUNTEER CORPS

Light Horse 1st Forfarshire Surgeon Captain T. F. Dewar, M.B., from the 1st Devonshire Volunteer Artillery (Western Division, Royal Artillery), to be Surgeon Captain (dated March 4th, 1893) — *Artillery* 1st Lanarkshire The undermentioned Surgeon Majors to be Surgeon Lieutenant-Colonels — G. R. Mather, M.D. and J. Provan, M.D. (both dated March 4th, 1893), Archibald Kerr Chalmers, M.D., to be Surgeon Lieutenant (dated March 4th, 1893) — *Rifle* 2nd (Prince of Wales) Volunteer Battalion the Devonshire Regiment Surgeon Lieutenant E. G. Dutton resigns his commission (dated March 4th, 1893) — 2nd (Berwickshire) Volunteer Battalion, the King's Own Scottish Borderers Surgeon Lieutenant S. Macvie, M.B., to be Surgeon Captain (dated March 4th, 1893) — 3rd (Dumfries) Volunteer Battalion, the King's Own Scottish Borderers Surgeon Captain A. D. MacDonald, M.D., to be Surgeon Major, and Surgeon Lieutenant J. MacLachlan, M.B., to be Surgeon-Captain (both dated March 4th, 1893) — 4th Volunteer Battalion, the Cameronians (Scottish Rifles) Surgeon Captain J. Macfie, M.D., to be Surgeon Major (dated March 4th, 1893) 2nd Volunteer Battalion, the South Staffordshire Regiment Thomas Martland, Gent., to be Surgeon Lieutenant (dated March 4th, 1893)

VOLUNTEER MEDICAL STAFF CORPS — The Norwich Company Frederick Preston, Gent., to be Surgeon Lieutenant (dated March 4th, 1893)

THE FEVER AT PESHAWUR.

We alluded not long ago to the serious prevalence of fever in the Peshawur garrison and to the removal of the Royal Welsh Fusiliers to Nowshera in consequence of its relief by the 3rd Battalion of the Rifle Brigade. We learn that the Royal Welsh Regiment has greatly improved in health, but that there have been many cases of fever among the men of the Rifle Brigade since their arrival at Peshawur.

REINSTATEMENT OF SURGEON MAJOR KING

According to an announcement in the *Fort St. George Gazette*, we are extremely glad to learn that the services of Surgeon Major King, Indian Medical Service, are placed at the disposal of the Public Department. This means that the officer in question returns to civil employment, and that the justice and merits of his case have been established and recognised by the Indian Government.

ARMY RECRUITING

The subject of recruiting—apart from its national importance, for the maintenance and efficiency of the army concern everyone—has a special interest for the Army Medical Service. The report for 1892 has now been published and the results are generally satisfactory, as may be concluded from the fact that in January 1892, the army was nearly 5000 below its proper strength, whereas on Jan 1st, 1893, it was over 1300 above it. The blots are the number of special enlistments—that is the number of recruits accepted by special authority who are not up to the required standards of age or physical development—and the increased number of deserters, the bulk of whom are under one year's service. Recruiting has of late been carried on under more favourable circumstances. The facilities for discharged soldiers obtaining employment in civil life have been largely increased, the system of advertising has been developed, the soldier's comfort and position have been improved in every way, and these facts are beginning to be known. The system of dieting and cooking that has been recently introduced into the army has given rise to more contentment in its ranks and has relieved the State of a financial difficulty. We concur with the Inspector General of recruiting in thinking that the adoption of the principle laid down by the Imperial Government of Germany in 1885 would have an excellent effect—viz., that every soldier of twelve years' service discharged with a certificate of good service has a prescriptive right to probationary employment in a large number of positions under Government, his permanent appointment to which depends upon himself and on the qualities and character he exhibits as a probationer.

EXCHANGES ON THE INDIAN ROSTER.

It is announced in the Indian papers that applications from officers of the Army Medical Staff for permission to

effect an exchange on the Indian roster are to be submitted to the Principal Medical Officer of Her Majesty's Forces for the orders of the Commander in Chief in India, and applications to retire are to be forwarded through the same channel to the Military Secretary to the Commander in Chief.

OFFICIATING AND SUBSTANTIVE MILITARY MEDICAL APPOINTMENTS IN INDIA

When a surgeon colonel is appointed to officiate as a surgeon major general, or a brigade surgeon lieutenant colonel to officiate in the administrative medical grades of the Medical Service, he will receive the temporary rank of surgeon major general or surgeon colonel, as the case may be, and any time an officer may have officiated in the administrative grades of the Medical Service on full consolidated salary, should he be confirmed without reverting to his substantive rank, shall reckon as qualifying service for additional pension.

THE ARMY AND THE GOTHENBURG SYSTEM.

The Bishop of Chester, in introducing his Bill into the House of Lords on the retail sale of intoxicating liquors, made great use of the practice pursued in the army in illustration and support of his measure. The Gothenburg principle had been applied practically to the army in the canteen system and by the development of regimental and garrison institutes, with their many social and moral advantages to the soldier. The Bishop quoted General Goodenough to the effect that the army had been, in fact, without knowing it, for nearly thirty years following what is known to the public as the Gothenburg system, under which the profits from the sale of liquors are employed for the good of the community in promoting objects of approved utility for the men at large. He also quoted Sir George Chesney's testimony as to the growth and development of essentially the same system in India under Lord Roberts into what is known as the Soldiers' Institute or the Regimental Institute of the present day. There can be no doubt that these institutes have been productive of much good in the army serving in India, in promoting the cause of temperance and health and the diminution of crime. These institutes are, in fact, comfortable, well managed social clubs, where the soldier may obtain everything he requires at a reasonable price and of a wholesome unadulterated quality.

Correspondence.

"Andi alteram partem."

THE SIGNIFICANCE OF ALBUMINURIA A TYPICAL CASE

To the Editors of THE LANCET

SIRS—Even whilst reading the leading article in THE LANCET of last week under the above title I have been dealing with a case proposed for insurance in a leading society, which seems to me to bring the whole matter to a bearing of the most practical kind, and the details of which I should like to submit as briefly and impersonally as possible. Is there such a thing as "physiological albuminuria?" If there be, then it occurs to me that the following must be a case of the kind.

X—, aged twenty six years, a native of the Highlands, and preserving much of the appearance of such, applied for insurance on Feb 3rd, 1892, and was examined and reported on next day. It was ascertained that he had scarlet fever when nine years of age, and again a sore throat of some kind when seventeen or eighteen, but neither of these illnesses appeared to have left any deleterious consequences whatever, and his health otherwise was stated to have been good throughout. Examination in detail corroborated this impression in every particular but one. The heart, the pulse the lungs and air passages, the abdominal organs generally, revealed no trace of disease to physical diagnosis or by symptoms. There were no venereal antecedents. His habits were apparently unexceptionable—"glass of claret only occasionally"—for the most part a practical abstainer. He was a slender, dark complexioned subject, of perfectly healthy appearance, height 5 ft. 11 in., weight 10 st. 5 lb., girth of chest 31 in to 33½ in., in expiration and inspiration respectively. The family history was unexceptionable as regards the parents and grandparents, unless it be that the paternal grandfather died of cancer at fifty six. He is an only child. The urine at this date (Feb. 4th, 1892) presented the follow-

characters sp. gr. 1033 normal appearance to the eye, but a distinct trace of albumen, both to heat and microscopically (urine passed at 2 P.M.). My report was as follows: "I think this case must be postponed, so far, at least, as to any of the urine in detail as to the albuminuria. Apart from this I see nothing in the case to render the life insuranceable."

A second sample of urine was obtained on Feb. 12th which had exactly the same characters sp. gr. 1024. I then asked the inquiry in the hands of his medical attendant, and the general instruction that this was a question to be decided, not in the interests of the insurance office but of the proposer himself. The result was that he returned on Feb. 27th, 1892, with a verbal report that his medical attendant had found the urine to contain a trace of albumen on several occasions after I had notified the fact to him, but on other occasions had found it free—no exact statements as to the occasions or as to the cyclic character of the albuminuria. On this I reported further as follows: "This life is in every respect unexceptionable, if we can take it as a rule to be followed that a very small trace of albumen in the urine, other circumstances being favourable, is not to be a bar to insurance. I am not personally quite of that opinion though I admit circumstances under which accidental and occasional impregnations of serum albumen may not seriously damage a life from the insurance point of view. How far this is such a case will appear from the following summary. On Feb. 4th and again on the 12th I found the trace above mentioned in the urine of this gentleman. The same is the case to-day. Urine passed at half past three normal to appearance in all respects, but with quite unequivocal trace of albumen by heat with acetic acid and by Roberts's solution of magnesium sulphate with a microscop employed by the contact method." I then gave the medical attendant's verbal report as above, which he afterwards (Oct. 10th) reduced to writing as follows: "X— called me with a sample of his urine weekly during the months of May, June and July to examine for albumen. In every sample I was able by the ordinary tests to detect a very small amount. I kept him under treatment for that, and the quantity of albumen remained much the same. During the last two months I had several opportunities of examining his urine and found the quantity distinctly less, particularly so in the last two samples where I had a difficulty in detecting even the slightest trace."

At a quite recent date in the end of February, 1893, this proposer called once more at the office and passed a sample of urine, which did not differ in any essential particular from the preceding as examined by me. He brought the following note from his medical attendant: "X— has been supplying me with samples of his urine regularly every week or ten days since the date of last report. I have made a careful examination in every instance—microscopically and with the other tests for albumen—with the result that I am perfectly satisfied there is no kidney disease in his case. In several of the samples sent in I could not detect any albumen at all and the quantity, when it could be traced, was so insignificant that I consider it a waste of time to prolong the examination. Still, there the albumen remains, according to my examination in February 1893, exactly as it was in February 1892. I have already said, in public, at Birmingham and elsewhere in discussions on the subject that I cannot but regard the presence of serum albumen (reacting to heat and nitric acid) to this small extent and with this degree of persistency as a danger signal. If this statement of this case is disputed on anything like reasonable grounds by those who advocate a 'physiological albuminuria,' I may have something more to say on the subject. Meanwhile I do not wish it to be supposed that I think it follows from the expression used above that this man has Bright's disease, or that he is very likely to die soon. A danger signal may be a danger rather than a danger. Nay a danger signal may be disregarded and yet no train be wrecked. But still, there it is and from the insurance point of view I think it ought not to be disregarded."

I am, Sirs, yours faithfully

Glasgow March 7th, 1893. W. T. GAIRDNER, M.D.

PROGNOSIS IN ALBUMINURIA

To the Editors of THE LANCET

SIRS—Your excellent advice that the time has arrived for a thorough re-investigation of the prognosis of albuminuria will be shared by many men. I think that most help will be obtained

from men who have kept private records of their cases for years rather than from hospital or even insurance records. If some method could be devised for collecting and analysing these notes an invaluable stock of renal knowledge would be available. The prognosis of heart disease has received more attention than that of albuminuria, and it will be in the recollection of many that the former at the instigation of the Collective Investigation Committee, was ably introduced by Sir Andrew Clark and fully discussed at the annual meeting of the British Medical Association in Brighton in 1886. One starts in practice with a horror that every case of albuminuria is going to be fatal. After having scared a number of people needlessly one gradually settles down to a more hopeful view of the presence of albuminous urine, which is comforting to the patient and beneficial to the doctor. At present it is impossible to say how many cases of early albuminuria develop Bright's disease and how many recover, but there is a point which must have struck several men much engaged in private practice—namely, the small number of deaths that occur from Bright's disease compared with the large number of cases of albuminuria met with. This appears to support the view, at any rate indirectly, that a good number of people recover. Some years ago I wrote to THE LANCET in reference to the "loading" of albuminuric cases, either in respect to the adding of years or of money. A further method seems to be that in which no extra premium is charged, but if the assured die previously to the age to which, as a first class life he might be expected to live, an equivalent deduction should be made from the amount assured, the deduction decreasing every year the assured lives, and if the assured should live as long as a first-class life is expected to live, the debt would be finally extinguished, and the amount of the original assurance would be paid in full at his death.

I am, Sirs, your obedient servant,

Folkestone, March 7th, 1893.

W. J. TYSON

INCIDENTS IN CHLOROFORMISATION

To the Editors of THE LANCET.

SIRS—On Sunday, Feb. 19th, I performed circumcision on a boy of eleven years who had suffered for years from nocturnal incontinence. Dr Thorpe administered chloroform on a napkin. The boy was very frightened previously to the operation, but he took the anæsthetic without struggling and was speedily brought under. I had completed the operation, save the tying of the last stitch when my attention was drawn to the patient's breathing, the respiration was very shallow, and as I looked it ceased. The nurse, an experienced woman, immediately exclaimed, "Oh, he is dead!" Dr Thorpe quickly removed the boy's shirt which was his only article of clothing except his stockings and I seized the ankles drew them over my shoulders and, thus suspended carried him about as well as the limited dimensions of the room permitted. After some minutes of this I placed him on the bed and we performed artificial respiration drawing out his tongue at the same time. In about ten minutes we were rewarded by a faint gasp. The chest walls were very thin and the heart was noticed to be feebly beating though no pulse was felt. By continuing the artificial respiration the breathing improved, and the abdomen rose and fell with each respiration. The breathing however again died away, the abdominal wall was flat and perfectly still. Dr Thorpe then suspended him as before and carried him through the room for from five to ten minutes. I observed the face become congested, and once more we resumed artificial respiration, to which he again responded after what seemed an age, but again we were disappointed as respiration once more ceased. Four times in all was he suspended, the third time he vomited some unmanicured and undigested orange which was with difficulty removed from his throat. Finally, I left him breathing comfortably after three-quarters of an hour's exertion. From the commencement of the anæsthetic until the collapse was about twelve minutes and Dr Thorpe informed me the quantity of chloroform used was two drachms. The boy is now well.

I am, Sirs, yours truly

DONALD C. MARTIN, A.M., M.D.

Stourport March 7th 1893.

THE VACCINATION PROBLEM

To the Editors of THE LANCET

SIRS—Will you permit me to express a hope that medical practitioners will not lose sight of your suggestion with regard

to writing to their representatives in Parliament to oppose the repeal of the Act for accumulative penalties for non compliance with vaccination. There is now no time to be lost. I much wish copies of your able article in THE LANCET of May 14th, 1892, could be sent to each Member of Parliament. They will, of course, be inundated with the false statements of the anti vaccinationists. It is a great pity that there is not a league of vaccinationists to disseminate the truth.

I am, Sirs, yours faithfully,
Worcester, March 6th, 1893 WM WOODWARD, M D

DENTAL ADVERTISING

To the Editors of THE LANCET

SIRS—The agitation in reference to the suppression of dental advertising is, I think, hardly a judicious one, for the simple reason that it cannot possibly bear fruit. The General Medical Council must, of course, be fully aware that many were making a practice of advertising at the time that they were admitted to the Dental Register, and therefore have practically a vested interest in the manner in which they now pursue their profession. This body of men have given no under taking to subscribe to the so-called etiquette of the profession, and under any circumstances it would have to be shown that advertising *per se* was harmful, apart from the mere sentimental objections to it. Dentists, too, unlike the medical profession, have an appeal to the Courts, and their interests are so large that it would be highly improbable they would be disturbed. It is certainly a hardship that the new "L.D.S." is not able to compete on an equal footing with the mere "registered" men, but the remedy would surely not be found by inflicting an injustice on the latter body. Altogether the movement seems to me to be impracticable, and the present anomalous state of things can only be rectified by the course of time. An effort to obtain a better distinction between the "qualified" dentist and the merely "registered" one would be more reasonable at the present moment, and more likely to yield better results.

I am, Sirs, yours faithfully,
March 1st, 1893 A LOOKER ON

LIGATURE OF THE ANTERIOR TIBIAL ARTERY

To the Editors of THE LANCET

SIRS,—I read with much interest Mr A Pearce Gould's interesting case of ligature of the anterior tibial artery in THE LANCET of March 4th. My object in writing is to draw attention to the great success attending the practice advocated by Mr Gould during the American Civil War. Both Confederate and Federal surgeons tied the anterior tibial artery in cases of compound fracture of the bones of the leg with success. Assistant-Surgeon R O'Leary, P.A.C.S., reports in the November number of the *Confederate States Medical and Surgical Journal* for 1864 a successful case, and the Surgeon General, U.S.A., gives a summary of forty seven ligations of the anterior tibial artery, twenty six patients survived the operation. In seven cases, with four recoveries, the posterior tibial artery was likewise tied. In fifteen cases in which amputation was performed secondary bleeding took place, necessitating ligature of the vessel on the face of the stump. Twelve cases were treated by ligation of the artery at the seat of the injury, of these six recovered and six died, or required amputation—a much smaller percentage than the usual from ligation of arteries, for of the 1155 ligations recorded in the U.S.A., 684 died—a result not to be wondered at when we think of the hardships their wounded troops suffered during the retreats from Fredericksburg, the Peninsula, Manassas, Chancellorsville, and many other great battles. The tendency of the hardships endured during transportation to produce secondary hemorrhage is illustrated by Surgeon Branton's case occurring during the flight from Fredericksburg.

I am, Sirs, yours truly,
GEORGE FOY, F.R.C.S.I.
Cavendish row, Rutland square East, Dublin, March 4th, 1893

FAMINE AND TYPHUS FEVER IN BENCHASI—News has been received in Tripoli to the effect that famine and its common attendant, typhus fever, have been causing terrible mortality amongst the inhabitants of Benchasi, the Turkish African province of Berea.

NORTHERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENT)

Tyne Sanitary Authority

THE medical officer for the Tyne port sanitary authority, Dr H E Armstrong, has issued a most interesting report, especially as regards the cholera precautions necessary last autumn in consequence of the great inter-communication of the Tyne with foreign infected ports. As regards the work done it is only necessary to state that from Aug 30th to Nov 21st last a continuous inspection was necessary of 497 ships carrying 8059 passengers and hands, and, with few exceptions, these had come from cholera infected ports. Dr Armstrong speaks highly of the work of Dr Clark, Mr Webster, Drs Steegman, Marshall and others, but says very little about his own work and risks, but it is well known and remembered (at least by his professional *confrères*) that he did not spare himself during this trying period, and indeed he remained up a whole night with a cholera patient and only left the poor fellow when he died. It is a pity that Dr Armstrong's exertions have not been adequately appreciated by the Tyne sanitary authority.

The Knight Memorial Hospital, Blyth

The annual meeting of this new institution (which is a great advantage to Blyth and its vicinity) has been held. Dr Newstead says in his report that in all about 800 patients were treated. The financial condition of the hospital is satisfactory, but more subscriptions will be necessary to cope with the increasing population.

Small pox in Northumberland and Durham

Although there is nothing in the nature of an epidemic of small pox in the north, one hears from day to day of cases here and there. It has reappeared at Sunderland, as also in Durham city and Weardale. In most cases it can be traced to tramps and wayfarers. If anything could be done to stop the migrations of these unsettled "gentry" I believe that the disease would before long be stamped out.

Sad Accident to a Durham Grammar School Master

Many of the readers of THE LANCET who have been educated at the Durham Grammar School will be sorry to hear of the sad accident to Mr F A Ker, M.A., tutor of modern languages for several years at that school. Mr Ker, who was very fond of trapeze exercise, fell from the cross bar when practising last Thursday, and he received such injury to his spine that he died in two days in the Durham County Infirmary.

Sunderland

A successful effort was made last week to benefit the infirmary and other charities by the press and dramatic charity carnival, resulting in the sum of £170. Next year it is proposed to enlarge the scope of the attractions by having, as at Newcastle, a musical *matinée* as well. A correspondent of the *Sunderland Echo* says that of the thirty-nine surgeons practising in Sunderland forty two years ago there are only four now remaining.

Middlesbrough Asylum

At a meeting of the Middlesbrough Asylum Committee the architect to the Lunacy Commissioners was instructed to prepare plans for a lunatic asylum to be erected on the Marton estate and to provide accommodation for 220 beds and at the same time for a possible increase of eighty patients.

Newcastle on Tyne, March 9th

SCOTLAND

(FROM OUR OWN CORRESPONDENTS)

Edinburgh Medico-Chirurgical Society

At the meeting of this Society last week Dr John Duncan read a paper on the Surgical Treatment of Gall stones, in which he gave his experience of operation in ten cases. One of these there was only one death and the patient who died was an old and much worn out man. He regarded the operation as a suitable and a safe proceeding. The second paper was by Dr Rutherford Morison of Newcastle on Some Mistakes and Accidents in the Technique of Abdominal Operations. The paper was a very practical one, illustrated by Dr Morison's experience.

Aberdeen Asylum for the Blind Annual Report

The report for 1892 shows that forty seven blind persons had been employed in the workshop of the institution, and the sum disbursed in wages, for holidays, sick allowance &c., was £1353 18s 3d, this being the largest sum paid in any one year since the asylum was opened in 1843. Ten children had been educated and had received industrial training. The donations received during the year amounted to £524 18s 2d, being a decrease of £17 6s 8d. There was excess of expenditure over ordinary income of £376 8s 0½d.

Health of Aberdeen.

Last week there were notified 2 cases of measles, 6 of scarlet fever, 1 of typhoid fever, 2 of erysipelas and one of puerperal fever—total, 12 cases.

Medical Officers to Aberdeen Corporation Employees

This week the Aberdeen town council appointed Messrs J. A. R. Glennie, M.B., J. R. Levack, M.B., and J. Marnoch, M.A., M.B. Aberd., to be medical officers to their employees. These are new appointments and this is the first election.

Aberdeen University

Amongst the list of honorary graduates in Laws (LL.D.) issued this week are the names of Sir Frederic Bateman, M.D., F.R.C.P., and Professor Crum Brown, M.D. Edin., D.Sc., F.R.S. &c.

March 7th.

IRELAND

(FROM OUR OWN CORRESPONDENT.)

Small-pox

THE registrar of Lisburn District has reported that two fresh cases of small pox have occurred in his district. He has strongly recommended revaccination. None of the inmates in the houses will consent, though all the children in the infected houses are vaccinated.

Case of Opium Poisoning

A graduate of Trinity College committed suicide last week by taking a large quantity of laudanum. He was addicted to drink and was in the habit of taking laudanum. The druggist who sold the laudanum (two ounces) stated that he could sell it to any person so long as it was labelled "poison," which caused the coroner to remark that it was a very bad Act of Parliament which allowed the sale of laudanum without a medical man's certificate.

His Excellency the Lord Lieutenant has placed Dr. Sappell on the Commission of the Peace for the Borough of Drogheda.

March 7th.

PARIS

(FROM OUR OWN CORRESPONDENT.)

Microbeless Islands

DURING a recent sojourn in the Spitzbergen group of islands in the Arctic regions M. Couteaud took the opportunity of studying the bacteriological peculiarities of these ice-bound spots. Analysis of the air, water and soil of Spitzbergen brought to light the extraordinary poverty of these regions in bacteria. Whilst, according to Miquel, the air of the streets of Paris contains on an average 51,000 bacteria, that of the Arctic Seas contains only 3 per cubic metre. As to the water of Spitzbergen, not only is it devoid of any pathogenic micro-organisms whatever, but all bacilli are absent. In the water of the island of Jean Mayen, however, there were discovered the bacterium termo and a few short and mobile bacilli. The bacillus subtilis so commonly met with in the different countries of Europe, was undetectable in the soil of those regions. At Jean Mayen there was found in abundance a leptothrix composed of long filaments irregularly twisted about 1 µ in diameter, producing elliptical and highly refracting spores. This species grows on gelatine into dense colonies, which possess no liquefying properties, but develop during growth a characteristic brown colouration. Despite these obvious advantages I doubt if Spitzbergen will ever come to be regarded as a desirable sanatorium for microbe-ridden humanity.

A Delicate Problem

The *secret professionnel* is an important factor in the life of a French medical man, seeing that the divulging of any information that can possibly be ranged in that category renders the informant liable to a heavy penalty. No wonder, then, that this question is, in its various phases, periodically discussed by professional corporations. The Association Syndicale des Médecins de la Seine having recently taken into consideration the proper course to be pursued by a physician called in by the family to a case of abortion in an unmarried girl staying with her aunt, the patient having attained her majority, decided unanimously that the practitioner was bound to absolute secrecy as to the nature of the illness. M. Le Blond maintained, however, that should the doctor be called in by the family they should be told the truth, but that if the young girl has herself sent for him it is his duty to keep the secret. If the girl be a minor, the family should, according to M. Petit-Vendol, be told the truth.

Phthysical Patients in Paris Hospitals and their Cost

A special hospital for phthysical patients corresponding with your own Brompton establishment does not exist in Paris. Traverse any of the medical wards in the general hospitals and you will find a large proportion of the beds occupied by poor sufferers from pulmonary tuberculosis. Apart from the acknowledged danger of infection thus thrust upon the other occupants of the wards, it has long been felt that it is not fair to the population to perpetuate this monopoly of beds by patients who, apart from the better nourishment offered them in hospital, derive very doubtful benefit by their sojourn in a germ-laden atmosphere. In a recent article on the subject M. Letulle (*Revue d'Hygiène*) gives some figures which speak for themselves. His investigations were limited to three hospitals during the year 1891.

Hospital.	Total No admitted on medical side	Phthysical patients.	Total deaths	Deaths from Phthisis
St. Antoine	11,680	1960	1433	525
Beaumont	6,169	554	723	234
Charité	—	1055	547	229

At St. Antoine, of 271,076 days in hospital, 55,200 are absorbed by phthysical cases, entailing an expense for the latter's maintenance of 154,560 francs out of 759,012 francs (the total expense). At the Charité, 31,816 out of 135,489 days in hospital are apportioned to phthysical patients, the cost being for them 108,174 francs out of a total of 460,662 francs. From the above figures it is seen that at least one fifth of the days in hospital and of the total cost is taken up by phthysical patients. Can anybody truly say that the result is anything like commensurate with the cost and with the sufferings entailed on disappointed candidates for admission? And how many originally phthisis free patients contract phthisis during their stay in wards thus contaminated?

March 7th.

BERLIN

(FROM OUR OWN CORRESPONDENT.)

Cholera in Prussia

A MEMORIAL regarding the measures taken against cholera attacks was laid before the Prussian Lower House the other day, and from it the following items may be taken.—The number of cases reported in Hamburg before the end of 1892 was 18,008, that of the deaths 7622. In all probability the epidemic was due to the fact that the water of the Elbe at the place at which it flowed unfiltered into the conduits of the city was infected. "It is almost absolutely certain that the comparatively small numbers of cases and deaths (578 and 331) in the city of Altona, which is immediately connected with Hamburg, the streets of the one being uninterrupted prolongations of those of the other, and which does not differ from that city in any of the vital conditions concerned, were due solely to the superiority of the water supply. The percentage of death in Hamburg was 1/24 in Altona 0/23." Special attention is drawn to the infecting of rivers and canals by barges, which carry with them infected bilge water and discharge it into uninfected waters, not to mention the fact that their inmates take their water indiscriminately from the rivers and empty their refuse into them. In Berlin there were only thirty-two cases, seven of the patients came from Hamburg by land, fourteen were inmates of barges, and

the remaining eleven cases were mostly directly traceable to the water of the Spree. As regards the prospects for the future, the memorial says "Unfortunately it cannot be said that cholera was extinct in Prussia at the end of 1892, for several cases imported from Hamburg occurred in Altona in the last week, and, considering the present state of the epidemic in Hamburg, invasions from there are still to be feared. The same danger threatens from the neighbouring western and eastern countries, for in the last week of the year cases were reported from the north of France and the Netherlands and from the Russian Polish Governmental districts of Radom, Lublin, Warsaw, Plock and Lomza. It is also possible that in Prussia itself germs emanating from last year's cases have remained undestroyed and that, after lying latent for an indefinite time, they may again develop under more favourable conditions and cause a new epidemic."

The German naturalists and medical men will hold their annual meeting in Nuremberg from Sept 11th to Sept 16th. Professor von Helmholtz will deliver an address.

It is expected that the Sanitary Conference in Dresden will be opened next Saturday, the 11th inst.

The city of Berlin intends to build a fourth hospital, but the project is still in a very preliminary stage.

March 5th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

On the Use of Benzozol in Diabetes Mellitus

BENZOSOL or benzoyl guaiacol, which has been introduced by Dr Bougarts as a substitute for creosote and guaiacol, has recently been recommended as a very useful remedy in diabetes mellitus by Dr Piatkowsky of Cracow. It is administered in doses of one to three grammes per diem. According to a recent communication at a meeting of the physicians at Prague by Professor Jaksch, the sugar disappeared from the urine after the administration of benzozol for eight days in the case of a female patient aged fifty-six years who had 5.7 per cent of sugar, but the patient died in consequence of a toxic enteritis with grave jaundice, which was attributed to the use of the remedy. On the other hand, it has been pointed out by a Vienna chemist that caution must be exercised with regard to the polarimetric examination of the urine in cases where benzozol has been administered, as the urine of persons who have taken this drug polarises to the left and therefore the polarimetric examinations of the urine of such persons, when it contains sugar, are misleading.

Cholera in Austria Hungary

No case of cholera has occurred in the empire during last week. The total number since the outbreak of the epidemic at Budapest is stated to have been 1063. Of these 604 recovered, whilst 459 died. Real Asiatic cholera could be determined only in 810 of these cases.

New Medical Institutes

At a recent meeting of the Austrian Parliament the Minister of Public Instruction promised that the erection of the new Physiological Institute and of the new Surgical Clinic of Professor Billroth would soon be commenced.

March 6th.

OXFORD UNIVERSITY AND INFECTIOUS DISEASES—

The Convocation of Oxford University was on Tuesday last engaged in discussing a question of some difficulty in connexion with the proposal to erect a fever hospital adjoining the City Hospital. It appears that the authorities of the Radcliffe Infirmary had determined to close its wards for infectious cases, so that it became necessary that provision should be made for such cases elsewhere. The scheme provided that the new hospital, with twelve beds, should be administered by the committee of the Sarah Acland Home and that the cost of its maintenance should fall upon the undergraduates. The proposal was criticised adversely by Dr Collier, who preferred an iron and wooden structure for the purpose suggested rather than a costly permanent building. The question of site with regard to its healthfulness was also made a matter of dispute. Sir Henry Acland confessed to having great difficulty in deciding for himself how he ought to vote in the matter, and ultimately the proposal was rejected by a majority of 43 against 33.

Obituary.

JAMES ANDERSON, M.A., M.D. ABERD., F.R.C.P. LOND.

It was with great regret that we last week intimated the sudden and premature death of Dr James Anderson, after an illness of about thirty hours' duration. We now give a brief outline of his life—a life in which it will be seen that the foundations of success were laid in most careful preparation and much hard work. Dr James Anderson was born in the year 1853 in the parish of Logie Buchan, Aberdeen shire, where his father was a farmer and grain merchant. The family consisted of three brothers and two sisters, the subject of this notice being the second brother. His father went to Australia to push his fortune, and died there within a short time. Upon the mother, therefore, devolved the care and upbringing of the family, and James Anderson was ever ready to acknowledge how much he owed to his mother. She was a woman of rare gifts, uniting a strong intelligent mind and much good sense with great tenderness and depth of feeling. Between mother and son the bond of affection was of the strongest and deepest. After being some time at the parish school James Anderson entered Gordon's Hospital School, where he was retained for six years as a most promising pupil to be sent up to the university. Having gained a bursary in the Faculty of Arts, he entered the University of Aberdeen. His course in Arts was very distinguished, his place in all the classes being very high, and in 1873 he took his degree of M.A. He carried off the gold medal as the best student of his year, and also the Murray scholarship—a scholarship tenable for three years and enabling its holder to prosecute scientific study. The above record is in itself a remarkable one, but it becomes far more so in Dr Anderson's case from the fact that during all his university course he was obliged to engage in laborious private teaching, which so filled up his time that his own work was done mainly in the hours that should have been given to sleep. The habit thus formed of doing without sufficient sleep and of carrying on his work far into the night grew upon him in later years and undoubtedly impaired a constitution never the most robust. Dr Anderson pursued his course of medical study with equal distinction, taking a first place in almost all his classes and graduating M.B., O.M., with highest academical honours in 1877. During the next two years he was demonstrator of anatomy under Professor Struthers, and at the conclusion of that time he went to Berlin and Vienna, where he spent a year in study, mainly in the special departments of ophthalmology, laryngology &c. He then settled in London, was for a time clinical assistant at the Royal London Ophthalmic Hospital and at the Hospital for Skin Diseases, Blackfriars, and shortly afterwards was appointed a demonstrator of anatomy at the London Hospital. In 1881 he became a Member of the Royal College of Physicians of London, and received the appointment of assistant physician to the City of London Hospital for Diseases of the Chest—an appointment which he held for some years. Dr Anderson was also appointed medical registrar at the London Hospital, upon which followed in 1886 his appointment as assistant physician to that hospital, where likewise, at the time of his death, he was lecturer on pathology. In 1888 Dr Anderson was elected assistant physician to the National Hospital for the Paralyzed and Epileptic, Queen's square, and only a week or so ago he became full physician to that institution. He was formerly an examiner in physiology and natural history in the University of Aberdeen, and a member of the Examining Board of the Royal College of Physicians of London and of the Royal College of Surgeons of England. He had held the offices of secretary to the Ophthalmological and Neurological Societies, was a Fellow of the Royal Medical and Chirurgical Society, and a member of the Pathological and Clinical Societies. He was for a time joint editor of the *Ophthalmological Review*, and was the author of the article "Epilepsies and Insanities" in Tuke's Dictionary of Psychological Medicine and of "Abnormalities of the Kidney" in Kailfo's "Diseases of Kidneys." He devoted a great deal of time to clinical teaching at the hospitals with which he was connected, and this, together with his increasing private practice, made it impossible for him to write much, but he had published some valuable papers in medical journals, chiefly upon ophthalmological and neurological subjects. Any

latter pertaining to his old university bad for him the reatest interest. He was one of the founders of the Aberdeen University Club, London, and amongst the last letters he wrote was one relating to the portrait of his old friend and teacher, Professor Struthers. Dr Anderson's illness was sudden and of brief duration. His mother's death, just a year ago, was a great trial to him, and he hardly seemed the same man after it, but yet, on Sunday, Feb. 26th, he appeared to be in his usual health and made no complaint of illness. When his servants retired for the night he was writing in his study, and he posted his letters between 2 and 10 o'clock. After that time he was seized with diarrhoea, leading to syncope and followed by pleuro-pneumonia, and he was found in his study in the morning in a state of collapse. He never fully rallied. The heart failure continued and became more marked. There was intestinal hæmorrhage and rapid engorgement of the lungs. He died at eight o'clock on Tuesday morning, Feb. 28th. As a man, as a teacher, as a physician and as a friend, Dr James Anderson was beloved by all who were privileged to know him. His intense love of truth, his pure-mindedness, his unselfish and unobtrusive kindness and his sympathy endeared him to all who came in contact with him. Although often weary with the burden of his own work, his sympathetic nature never refused help or advice to those who sought it. The young student, the busy practitioner and the old personal friend, all alike went to him with their troubles, and were sure not only of a ready response and of sympathetic interest but of wise counsel and of practical help. In the hearts of his friends his place can never be filled.

One of his colleagues, who knew him well, writes—"Dr James Anderson's death is a bitter calamity for his numerous friends. The suddenness of his decease in the midst of what seemed to most energetic vitality makes his loss the less bearable to those intimately associated with him. There is something of irreplaceable value torn out of their lives. He was too good a man to be bedizened with laudatory adjectives. To say that he was honourable and that he was courageous in right conduct is to apply words which, from lavish use, have lost much of their definite meaning. But to those who knew Anderson well they, applied to him, who was the embodiment of straightforwardness and rectitude, fill out with meaning. He was a bright example of what a medical man should be in his endeavours for success, I do not mean a commonplace success, but that to be earned by good work, done without mere personal aims, and not done only on lines of conventional ambition. Bacon wrote 'I hold every man to be a debtor to his profession, from the which, as men of course do seek to receive countenance and profit, so ought they of duty to endeavour themselves by way of amends to be a help and ornament thereunto.' Anderson certainly did his work as if he felt himself a debtor to his profession. Very many men will find themselves more able practitioners and more worthy members of our great profession in consequence of his teaching and example. Anderson will live in their grateful memory. Let it be a pain to think that one so endowed naturally, disciplined so greatly by a severe intellectual training and so well equipped with most varied technical knowledge, should have left behind him on printed record so little to testify to those who did not know him personally his intellectual power and moral worth. I say moral worth in this regard in respect of scientific work. For love of accuracy and truthfulness are not really so distinct as popular speech makes them out to be. A love of accuracy is as much a moral as an intellectual quality. Anderson in his daily medical work was never anxious to be definite when accuracy was impossible, would not speak as if he knew when he could only suppose, and did not take a simple view of a complex case by ignoring its difficulties. Yet he had nothing in common with the Philistine who talks of facts as if they had no relation to general principles—facts *in vacuo*."

Dr Struthers writes—"My acquaintance with Dr James Anderson began in the summer session of 1873, when he commenced his medical studies on the conclusion of his four years arts course in the university. He had been a distinguished student in arts, and at the end of the course had awarded him the gold medal given by the magistrates and town council of the city to the most distinguished scholar at the termination of the arts curriculum, and he had gained the valuable Alexander Murray Scholarship, open to competition amongst all the graduates in arts of the last three years, tenable for three years. During the three years he was in the anatomy class he was first prizeman in each year in the various stages and branches,

and in the third year in regional anatomy. He was recognised as the leading student in my class during all that time, and I may say in the medical school generally, his name, I see, occurring repeatedly as first prizeman in other classes. Besides the natural ability and working habit which gained him these distinctions he showed already as a student the qualities of character for which he was remarkable in after life. He graduated in medicine in April, 1879—I need hardly add, with 'highest honours'—and I had no hesitation in selecting him at once for the responsible position of demonstrator of anatomy. The various duties of that position he discharged most ably, having charge of the dissecting room as chief assistant, conducting entirely an osteology class for beginners, conducting with me the summer laboratory course of practical histology, and when I had occasion to be absent he took my place in the lecture-room. I could trust Dr Anderson in every way, not only for his ability and attainments, but for his conscientiousness and his high sense of honour. It was a great regret to me when the inevitable time for his leaving came, for there was no fit career for him in Aberdeen. Before going to London he went for further clinical experience to Berlin and Vienna, accompanied by his friend, Dr Alexander Macgregor now of Aberdeen, who had been junior demonstrator with him in anatomy. In London Dr Anderson attached himself to the London Hospital, beginning as demonstrator of anatomy, where his work was soon recognised by Sir Andrew Clark, Dr Stephen Mackenzie, Mr Treves and other members of the staff. The various appointments Dr Anderson held at the London Hospital and its school, and elsewhere in London, and the position he had made for himself in London, are well known. During these twelve or thirteen years of his London life I have seen him from time to time and have observed in him the development of the same qualities that he showed in his time with me, his devotion to work, his remarkably judicious mind, his composed, unassuming manner and his kindness of heart. Dr Anderson's progress in the arduous aim at position as a London physician was rapid, the more so considering that he began as a stranger there, and it would have been surprising to me had I not known his ability and character. Years ago from what he told me when he removed to his house at Wimpole-street he already had his foot firmly on the ladder of consulting practice, and I do not doubt that he would have attained to the highest rank in that position. His early death is a profound grief to all who knew him personally, and it may without exaggeration be said that the death of such a man is a loss to the medical profession. That one so physically strong as Dr Anderson was should have fallen so early may appear surprising. I am led by his death to think of the number of able and most promising assistants I have had both in Edinburgh and Aberdeen who have gone down in early life. There are limits to the extent to which even an iron frame can stand long years of constant overwork, day and night. When to that is added the London atmosphere and the consideration that the younger men of the hospitals are often kept on duty too much in the autumn when their seniors who have survived the ordeal are having their well earned holiday early breakdown need not be surprising. I trust that steps will be taken to perpetuate Dr James Anderson's name in some suitable way at Aberdeen and at the London Hospital School."

Dr Johns who was housephysician to the late Dr Anderson, supplies the following. As assistant physician, with the charge of out-patients and with fifteen beds for in patients, Dr Anderson was brought much in contact with the students, and it was his ambition to bring himself into touch with all who worked with him. It was the ready sympathy which he showed to all with the difficulties of their professional work, and the kind attention he gave to personal troubles, however apparently trivial, together with the soundness of his advice, that so completely endeared him to all who had the privilege of coming into contact with him. As a teacher in the out-patient department he was unsurpassed for the rigid thoroughness of his methods of examination, with a most emphatic manner of impressing the important features of each case on his hearers. He himself a most earnest student and thorough in every detail of examination and inquiry would allow no half measures among those working with him, and by his very example roused a spirit of enthusiasm like his own. In the out-patient department he constantly, tired with the work of a heavy afternoon, would, after the last case had been seen in spite of the calls on his time devote an hour or more to a short clinical lecture on methods of examination and diagnosis, emphasising his remarks by

theremaining eleven cases were mostly directly traceable to the water of the Spree. As regards the prospects for the future, the memorial says "Unfortunately it cannot be said that cholera was extinct in Prussia at the end of 1892, for several cases imported from Hamburg occurred in Altona in the last week, and, considering the present state of the epidemic in Hamburg, invasions from there are still to be feared. The same danger threatens from the neighbouring western and eastern countries, for in the last week of the year cases were reported from the north of France and the Netherlands and from the Russian Polish Governmental districts of Radom, Lublin, Warsaw, Plock and Lomza. It is also possible that in Prussia itself germs emanating from last year's cases have remained undestroyed and that, after lying latent for an indefinite time, they may again develop under more favourable conditions and cause a new epidemic."

The German naturalists and medical men will hold their annual meeting in Nuremberg from Sept. 11th to Sept. 16th. Professor von Helmholtz will deliver an address.

It is expected that the Sanitary Conference in Dresden will be opened next Saturday, the 11th inst.

The city of Berlin intends to build a fourth hospital, but the project is still in a very preliminary stage.

March 5th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

On the Use of Benzosol in Diabetes Mellitus

BENZOSOL or benzoyl guaiacol, which has been introduced by Dr Bougarts as a substitute for creosote and guaiacol, has recently been recommended as a very useful remedy in diabetes mellitus by Dr Platkowsky of Cracow. It is administered in doses of one to three grammes per diem. According to a recent communication at a meeting of the physicians at Prague by Professor Jaksch, the sugar disappeared from the urine after the administration of benzosol for eight days in the case of a female patient aged fifty six years who had 5.7 per cent of sugar, but the patient died in consequence of a toxic enteritis with grave jaundice, which was attributed to the use of the remedy. On the other hand, it has been pointed out by a Vienna chemist that caution must be exercised with regard to the polarimetric examination of the urine in cases where benzosol has been administered, as the urine of persons who have taken this drug polarises to the left and therefore the polarimetric examinations of the urine of such persons, when it contains sugar, are misleading.

Cholera in Austria Hungary

No case of cholera has occurred in the empire during last week. The total number since the outbreak of the epidemic at Budapest is stated to have been 1063. Of these 604 recovered, whilst 459 died. Real Asiatic cholera could be determined only in 810 of these cases.

New Medical Institutes

At a recent meeting of the Austrian Parliament the Minister of Public Instruction promised that the erection of the new Physiological Institute and of the new Surgical Clinic of Professor Billroth would soon be commenced.

March 6th.

OXFORD UNIVERSITY AND INFECTIOUS DISEASES—

The Convocation of Oxford University was on Tuesday last engaged in discussing a question of some difficulty in connexion with the proposal to erect a fever hospital adjoining the City Hospital. It appears that the authorities of the Radcliffe Infirmary had determined to close its wards for infectious cases, so that it became necessary that provision should be made for such cases elsewhere. The scheme provided that the new hospital, with twelve beds, should be administered by the committee of the Sarah Acland Home and that the cost of its maintenance should fall upon the undergraduates. The proposal was criticised adversely by Dr Collier, who preferred an iron and wooden structure for the purpose suggested rather than a costly permanent building. The question of site with regard to its healthfulness was also made a matter of dispute. Sir Henry Acland confessed to having great difficulty in deciding for himself how he ought to vote in the matter, and ultimately the proposal was rejected by a majority of 43 against 33.

Obituary.

JAMES ANDERSON, M.A., M.D. ABERD., F.R.C.P. LOND.

IT was with great regret that we last week intimated the sudden and premature death of Dr James Anderson, after an illness of about thirty hours' duration. We now give a brief outline of his life—a life in which it will be seen that the foundations of success were laid in most careful preparation and much hard work. Dr James Anderson was born in the year 1853 in the parish of Logie Buchan, Aberdeen shire, where his father was a farmer and grain merchant. The family consisted of three brothers and two sisters, the subject of this notice being the second brother. His father went to Australia to push his fortune, and died there within a short time. Upon the mother, therefore, devolved the care and upbringing of the family, and James Anderson was ever ready to acknowledge how much he owed to his mother. She was a woman of rare gifts, uniting a strong intelligent mind and much good sense with great tenderness and depth of feeling. Between mother and son the bond of affection was of the strongest and deepest. After being some time at the parish school James Anderson entered Gordon's Hospital School, where he was retained for six years as a most promising pupil to be sent up to the university. Having gained a bursary in the Faculty of Arts, he entered the University of Aberdeen. His course in Arts was very distinguished, his place in all the classes being very high, and in 1873 he took his degree of M.A. He carried off the gold medal as the best student of his year, and also the Murray scholarship—a scholarship tenable for three years and enabling its holder to prosecute scientific study. The above record is in itself a remarkable one, but it becomes far more so in Dr Anderson's case from the fact that during all his university course he was obliged to engage in laborious private teaching, which so filled up his time that his own work was done mainly in the hours that should have been given to sleep. The habit thus formed of doing without sufficient sleep and of carrying on his work far into the night grew upon him in later years and undoubtedly impaired a constitution never the most robust. Dr Anderson pursued his course of medical study with equal distinction, taking a first place in almost all his classes and graduating M.B., O.M., with highest academical honours in 1877. During the next two years he was demonstrator of anatomy under Professor Struthers, and at the conclusion of that time he went to Berlin and Vienna, where he spent a year in study, mainly in the special departments of ophthalmology, laryngology &c. He then settled in London, was for a time clinical assistant at the Royal London Ophthalmic Hospital and at the Hospital for Skin Diseases, Blackfriars, and shortly afterwards was appointed a demonstrator of anatomy at the London Hospital. In 1881 he became a Member of the Royal College of Physicians of London, and received the appointment of assistant physician to the City of London Hospital for Diseases of the Chest—an appointment which he held for some years. Dr Anderson was also appointed medical registrar at the London Hospital, upon which followed in 1886 his appointment as assistant physician to that hospital, where likewise, at the time of his death, he was lecturer on pathology. In 1888 Dr Anderson was elected assistant physician to the National Hospital for the Paralyzed and Epileptic, Queen's square, and only a week or so ago he became full physician to that institution. He was formerly an examiner in physiology and natural history in the University of Aberdeen, and a member of the Examining Board of the Royal College of Physicians of London and of the Royal College of Surgeons of England. He had held the offices of secretary to the Ophthalmological and Neurological Societies, was a Fellow of the Royal Medical and Chirurgical Society, and a member of the Pathological and Clinical Societies. He was for a time joint editor of the *Ophthalmological Review*, and was the author of the article "Epilepsies and Insanities" in Tuke's Dictionary of Psychological Medicine and of "Abnormalities of the Kidney" in Ralfe's "Diseases of Kidneys." He devoted a great deal of time to clinical teaching at the hospitals with which he was connected, and this, together with his increasing private practice, made it impossible for him to write much, but he had published some valuable papers in medical journals, chiefly upon ophthalmological and neurological subjects. Any

alluding to the cases of interest which had recently been treated. To these lectures, and by watching and trying to follow Dr Anderson's methods, many of us owe what is best in our knowledge of diagnosis and treatment. As a demonstrator of morbid anatomy he was most popular for his careful and accurate examinations, always ready to give, and indeed inviting criticism of his remarks that he might give, the reasons for all his statements and thus impressing the truth of his words on his hearers. That he was popular as a lecturer on pathology can be gathered when we are told that, though following such an esteemed and eloquent lecturer as the late Dr Sutton, the theatre was crowded for his lectures, not only by the men in the college but by men qualified and unqualified of all years, and his words followed by as much attention as was accorded to his unrivalled predecessor. His popularity as a lecturer was not confined to the students. As lecturer to the nursing staff his loss is felt by every nurse and sister in the hospital, and his knowledge of all the minor details of nursing was remarkable. With regard to the students generally he was a universal favourite from his absolute straightforwardness. He invited the confidence of all about him by proving himself worthy of it, and I am but expressing the feeling of my fellow students when I say that we have not only lost a great teacher but a friend."

A meeting was held on Tuesday at 16 Cavendish square, for the purpose of considering the advisability of instituting some memorial of the late Dr James Anderson. There was a large attendance, and amongst those present were Sir Andrew Clark, Mr Hutchinson, Mr Nettleship, Drs Hughlings Jackson, Ormerod, Stephen Mackenzie, Fernier and Mitchell Bruce. Touching reference was first made to the loss the medical profession had sustained through Dr Anderson's untimely death. The meeting then expressed itself as strongly in favour of the proposed memorial being founded, and resolved, if possible, to coöperate with a similar movement which has been started in Aberdeen. The following committee was then appointed to carry out the preliminary arrangements—Sir Andrew Clark (chairman), Dr Hughlings Jackson, Dr Ormerod, Dr Fernier and Dr Gilbert Smith. Dr Burnet and Dr Fitzgerald were appointed honorary secretaries.

At a meeting of the Aberdeen University Council on Saturday last Principal Sir William Geddes referred to the death of this distinguished graduate. He had attained, he said, by his own energy, skill and perseverance in the path of duty, almost the highest rank in his profession in the metropolis, and to them, in their alma mater, he was memorable as a typical example of the cultured physician—a fine specimen of what the combined training in arts and medicine at Aberdeen could enable a man to achieve. Eminent Professor Alexander Bain, LL.D., also spoke of the sudden loss of this distinguished physician, and alluded to the melancholy interest attaching to one of Dr Anderson's last remarks to him: "I shall be very happy if my system at seventy-two is found as good as yours."

PROFESSOR BENJAMIN BALL (OF PARIS)

ON Sunday, the 26th ult., the remains of Dr Benjamin Ball, Professor of Mental Medicine at the Paris Faculty and Physician to the Laennec Hospital, were laid in their final resting place. Professor Ball's last appearance as a lecturer was at the St. Anne's Asylum on Jan. 17th, 1892, the subject being "La folie politique." Since the 22nd of that month he had been incapacitated from work, his place in the chair of Mental Medicine and as Physician to the Laennec Hospital being provisionally taken by Dr Ballet and Dr Petit respectively. For some months before his death he was aphasic, but up to the very last his intellectual faculties remained intact and he was able to sign his name shortly before the fatal dénouement. After a short service performed by the Protestant pastor, M. William Monod, at the late Professor Ball's residence, 35 Rue des Martyrs—a very appropriate name, seeing that he probably fell a victim to excessive mental strain—the funeral procession wended its way past the detachment of the 2nd Regiment of Marine Infantry in attendance in honour of the dead knight of the Legion of Honour, and finally deposited the remains in a vault in the Montmartre cemetery. Amongst the large body of mourners at the house and at the grave were nearly all the professors and *professeurs agrégés* of the Faculty in their picturesque robes including MM Charcot, Brouardel, Guyon, Farabeuf, Matthias Duval, Tarnier, Hayem, Tillaux, and M. Gréard, Vice Rector of the Academy of Paris,

together with many of Professor Ball's former *chefs de clinique*, internes and pupils. The pall bearers were Professor Brouardel, Dean of the Faculty, M. Darboux, Dean of the Academy of Sciences, Dr Peyron, director of the Assistance Publique, and Dr Bergeron, representing the Academy of Medicine, of which the deceased was a distinguished member. In deference to the express wish of the deceased, the usual French custom of delivering eulogistic speeches at the grave was omitted. The hearse was followed by deputations of nurses from Laennec Hospital and St. Anne's Asylum in caps and aprons. Huge wreaths of natural flowers, chiefly Parma violets, were conspicuous in the procession, the senders being the Association des Étudiants, the nurses above mentioned and his old pupils, the inscription on the latter wreath being *A leur Professeur Ball*.

Benjamin Ball was born at Naples on April 20th, 1833, his father being English and his mother Swiss, a scion of the ancient Huguenot family of Autran. Naturalised as a Frenchman in 1849, he became an *externe* in 1854, an *interne* in the following year and *chef de clinique* in 1863. During his *internat* he was *lauréat des hôpitaux* and Laureate of the Academy of Medicine (Prix Portal, in collaboration with M. Charcot). In 1866 he became *professeur-agrégé*, his thesis being entitled "Du Rhumatisme Viscéral et du Rhumatisme Cérébral." In 1870 he was appointed a hospital physician. Seven years later the new chair of Mental Medicine was created expressly for him. His lectures, delivered every Sunday morning in the theatre of St. Anne's Asylum, were remarkable for their lucidity and for the pure and beautiful idiomatic French in which they were couched. No wonder, then, that the theatre was always crowded to overflowing, all nationalities being represented amongst his delighted hearers. He quickly became idolised by students, to whom he was ever most kind. More especially was this the case with English and American students, who never failed to find in him a true friend. The following is as complete a list of the late Professor Ball's works as is available at the present juncture: "Leçons sur les Maladies Mentales" (900 pages, 1883), "De la Morphinomanie" (second edition, 1888), "De la Folie Érotique" (1 vol., 1887), "La Claustrophobie" (*Annales Médico-Psychologiques*, 1879), "Ischémie Cérébrale Fonctionnelle," "Les Impulsions Intellectuelles," "Phthisie et Folie," "La Torpeur Cérébrale," "La Stigmatisée de S—," "L'Insanité dans la Paralyse Agitante" (Congrès de Londres, 1881), "Le Crétin des Batignolles," "Les Familles des Aliénés," "Responsabilité Partielle des Aliénés," "L'Aliéné devant la Société," "La Folie du Doute," "La Dipsonomie," "Les Frontières de la Folie," "La Folie Gémellaire," "L'Hébéphrénie ou Folie de la Puberté," "La Folie à Deux," "Épilepsie avec Conscience," "Folie Consécutives au Choléra," and "Hallucinations de l'Oùle Consécutives à une Inflammation de l'Oreille Moyenne" (all the articles preceding were published in the *Encéphale*, which he founded and edited with M. Luys). In the *Dictionnaire Encyclopédique des Sciences Médicales* he wrote with M. Ritti on Delirium, and with M. Chambard on Acute Delirium, Delirium Tremens, Dementia, Sleep and Somnambulism. In the neuropathic field he contributed the following papers: "Des Arthropathies Lées," "L'Ataxie Locomotrice," "De l'Erythème Symptomatique des Tumeurs Cérébrales," "Mal Perforant du Pied dans l'Ataxie Locomotrice" (London Congress, 1881, in English), and "Tumeurs et Abscess du Cerveau." To these must be added eleven papers (including his Thesis for the Doctorate in 1866 on Pulmonary Embolism) on general medicine. Dr Ball was a Member of the Academy of Medicine, and corresponding member of learned societies in London, Lisbon, New York, Glasgow &c. Glasgow University conferred on him, on the occasion of the last meeting of the British Medical Association held there, the honorary degree of LL.D. He was very proud of this distinction. He spoke fluently no less than seven languages. Three years ago he presided at the annual banquet of the Continental Anglo-American Medical Society, and made on that occasion an admirable speech. Indeed, he always delighted in being surrounded by Englishmen, to whom he was particularly fond. He was an inveterate chess player. His house was always open to students, and it may truly be said that no larger hearted couple ever existed than Dr and Madame Ball. It may be mentioned that Madame Ball's father was M. Camier Belleuse, who after being Director of the Wedgwood Minton works at Stoke-upon-Trent, became Artistic Director of the celebrated Sèvres Manufactory. Her two brothers are well known artists. Dr Ball was for many years a valued contributor to the columns of THE LANCET.

MEDICAL TRIAL

ROYAL COLLEGE OF PHYSICIANS OF LONDON
AND GENERAL MEDICAL COUNCIL.

Is the action of the Royal College of Physicians of London claiming a declaration that at the date of the passing of the Medical Act, 1886 they were entitled to grant a diploma in respect of medicine and surgery, and to hold such qualifying examination in medicine surgery and midwifery as mentioned in the Medical Act of 1886 of which a summary appeared in THE LANCET of last week, judgment was delivered on Wednesday last by Lord Justice A. L. Smith as follows—

The question for determination is whether the defendants, the General Council of Medical Education and Registration of the United Kingdom are entitled to place upon the Register of medical practitioners the name of a Fellow, Member or Licentiate of the Royal College of Physicians of London, who produce to the defendants Registrar a diploma granted by the plaintiffs to practise physic, including therein the practice of medicine, surgery and midwifery. The answer to be given to this question depends upon this single point—viz. "Was the Royal College of Physicians of London at the date of the passing of the Medical Act, 1886 (49 and 50 Vict., c. 48) a medical corporation legally qualified to grant a diploma in respect of medicine and surgery?" It is not disputed that the applicant for registration in the present case had been efficiently examined by the plaintiff in each of these three subjects and that the requisite evidence as to this was forthcoming. The defendants admit that the plaintiff corporation is legally qualified to grant a diploma in respect of medicine, but the position they take up is that it is not a corporation legally qualified to grant a diploma in respect of surgery. By the Medical Act, 1853 (21 & 22 Vict., c. 90) the defendants, the General Council, were created, and it was therein enacted that a Register of medical practitioners should be kept. Section 14 prescribed the duty of keeping this Register, and Section 15 provided for the registration of practitioners. By this section every person thereafter becoming possessed of, amongst others the qualification of Licentiate of the Royal College of Physicians of London, became entitled to be registered on producing to the Registrar the document conferring or evidencing the qualification, whereof he sought to be registered, which in this case consisted of the diploma of the Royal College of Physicians of London, issued by them to their licentiate to practise physic, including therein the practice of medicine, surgery and midwifery. It will be noticed that it is upon the production of the diploma that the applicant is entitled to be registered and that the Medical Council under this Act could raise no question as to where, when, or in what the applicant had been examined. It is only by Sections 20 and 21, if the Council thought that the course of study and examination prescribed by any college or body was not sufficient, that they might intervene, and then could only make a representation thereof to the Privy Council, who might suspend the right of registration if it thought fit. The Medical Council could not refuse to register if the requisite diploma were produced. So matters continued for nearly thirty years down to the passing of the Medical Act of 1886 when for the first time it was enacted that no person should be registered under the Medical Acts in respect of any qualification unless he had passed a qualifying examination in medicine, surgery and midwifery, held by, amongst other bodies, "a medical corporation legally qualified at the date of passing of that Act to grant a diploma in respect of medicine and surgery." Was, then, the Royal College of Physicians of London such a corporation in 1886? That is the point. By charter granted by Henry VIII. dated Sept. 23rd, 1518 being the tenth year of his reign the President, and College, and Commonalty of the Faculty of Physic in London better known as the Royal College of Physicians in London, were incorporated to exercise medicine (Medicina) in the City of London and the suburbs and within seven miles from the City on every side. It was by this charter granted that no one in the City or for seven miles in circuit of the same, should exercise the faculty of medicine unless admitted thereto by letters of the President and Commonalty sealed with their common seal. By the 14th and 15th Henry VIII., c. 5 (1522) this charter was confirmed, and by Section 3 it was enacted that

no person from thenceforth be suffered to exercise or practise physic through England until such time as he be examined at London by the said President and three elects and to have from them letters testimonial of their approving and examination. There was an exception made in this Act in favour of graduates of Oxford and Cambridge. Eighteen years afterwards—viz., in 1540—an Act was passed (32nd Henry VIII., c. 40) relating to physicians and their privileges. Section 3 is most important, and I set it out at length "And forasmuch as the science of physic doth comprehend, include and contain the knowledge of surgery as a special member and part of the same, therefore be it enacted that any of the same company or fellowship of physicians may from time to time as well within the city as elsewhere within this realm, practise and exercise the said science of physic in all and every his members and parts, any Act, statute or provision made to the contrary notwithstanding." Here, it will be seen, is a direct recognition by statute that the science of physic comprehended included and contained the knowledge of surgery as a special member and part thereof, and that the statute granted to the Company or Fellowship of Physicians the privilege of practising such science of physic within the realm, notwithstanding any Act, statute or provision to the contrary. In my judgment this statute shows that the word "medicina," which, in English, is equivalent to the word "physic" at that time at any rate embraced the general art of healing, whether by drugs or surgery and was not confined to the healing by drugs as was argued on behalf of the defendants. It appears that from the earliest time down to recent date the diploma granted by the plaintiffs and their predecessors to their Fellows and Licentiates was as far as material, in the following form—"Ego A. B., Presidens hujus collegii, admitto ad medicinæ facultatem tam docendam quam exercendam." It is not denied by the defendants that the Fellows and Licentiates who obtained these diplomas have been accustomed to practise as general practitioners in medicine, surgery and midwifery, or in either as to them seem best. Sir Horace Davey for the defendants commenced with the Charter of 1st Edward IV. granted to the barbers and traced down the history of the surgeons from this through 3rd Henry VIII. (1511), an Act purporting to relate to the appointment and examination of persons to act as physicians and surgeons within the City of London and seven miles round (though when the Parliament roll was examined it was found that as the Act originally stood, upon the roll it applied solely to physicians and that the word surgeons for some reason or other had since been interpolated) through 32nd Henry VIII., c. 42 uniting the barbers and surgeons into one whole body corporate, through the Charter of 5th Charles I. granted to the surgeons and through 18th George II., c. 15 whereby the surgeons became incorporated and of which incorporation the Royal College of Surgeons is the direct successor, and through other Acts prior or subsequent thereto. He argued that from these documents, taken together with those cited by the plaintiffs, it appeared that there was the faculty of medicine as distinguished from the faculty of surgery, and he urged, and with force, that these two faculties from the earliest times had run upon totally different lines, and he urged that physicians had nothing to do with surgeons. He pointed out what I think was the fact, that although the College of Physicians from the year 1582 held lectures in surgery called Lumleian lectures that although their examinations prior to 1835 were 'In primis comities in parte Medicina Physiologica in secundis in parte Pathologica in tertius in parte Theurapentica'—which, Dr. Liveing said was as much in surgery as medicine, and since that date embraced the obstetric art and principles of surgery yet it was not till the year 1862 that the first real effective examination in surgery itself was made by the plaintiffs, who then called to their assistance Mr. Erichsen to examine, and since then they have ever had an eminent surgeon to aid them in the examination in surgery of those of their students whom they examined themselves. I should mention that since 1864 the plaintiffs in conjunction with the Royal College of Surgeons have held joint examinations of those students who had commenced their studies since that date, and these examinations still continue. Sir H. Davey argued that the construction placed by the Solicitor General upon Section 3 of the 32nd Henry VIII., c. 40 was erroneous. I incline to the opinion that Sir Horace Davey placed the correct construction upon this section when he insisted that the privileges granted by it were confined to the "company or fellowship of Physicians" which he read

as equivalent to "commonalty or fellows" of that body. But be this as it may, it does not affect the point as to whether the plaintiffs could grant a diploma in medicine and surgery. I think, too, that he was correct when he said that surgeons and physicians had run in distinct lines from the earliest time. But this is not what I have to decide. The point is, were the plaintiffs a Medical Corporation in 1886 legally qualified to grant a diploma in respect of medicine and surgery? The Solicitor General's reply to the argument of Sir H. Davey appears to me conclusive. He said, "For the purposes of this case, I accept Sir H. Davey's reading of the section, for he admits that the plaintiffs could grant a diploma to their commonalty or Fellows, to practise in medicine and surgery, and," said the Solicitor General, "that is all that is required, for this brings the plaintiffs within the exact terms of the Act—viz., a Medical Corporation legally qualified to grant diplomas in respect of medicine and surgery." He said, "whether physicians and surgeons ran in different grooves did not affect the point to be determined." In my judgment the Solicitor General is right when he says, "Once got the Corporation legally qualified to grant the diploma, and then they are the persons who are designated by the statute to hold the examination." This argument appears to me to be unanswerable. It has been established that the plaintiffs were at the date of the passing of the Act of 1886 a corporation legally qualified to grant diplomas in respect of medicine and surgery, and that in my judgment concludes this case. For these reasons, in my opinion, the plaintiffs are right and are entitled to judgment and the declaration asked for, and they must have the costs of the action.

Sir H. Davey, Q.C., asked what would be the terms of the declaration.

Sir Arthur Watson, Q.C., thought they should be in the words of the statement of claim.

Sir H. Davey. All we want is that the plaintiffs themselves are a Medical Corporation legally qualified to grant diplomas in medicine and surgery.

Sir A. Watson. There is no objection.

Sir H. Davey. The statement of claim is rather aggressive in its tone. You do not ask for an injunction.

Sir A. Watson. After what Sir Horace Davey has said, I cannot imagine as to the body he represents that that course would be necessary.

Lord Justice Smith. It was merely a friendly suit, I take it.

Sir A. Watson. Then, my lord, the declaration, with liberty to apply?

Lord Justice Smith. Very well. I have no doubt these gentlemen will do what is right.

Judgment accordingly.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At an ordinary meeting of the Council of the College held on Thursday, the 9th inst., the President, Mr. Thomas Bryant, occupied the chair.

The Secretary reported the death, on Jan. 12th last, at the age of seventy-eight, of Mr. Alfred Baker, past member of the Council, and the Council unanimously recorded their deep regret at the death of one whom they highly esteemed, both as a colleague and as a member of the profession, and expressed their sympathy with his widow and family in their bereavement.

The Council elected Mr. H. P. Dean an examiner in Elementary Biology under the Combined Examining Board in England.

The following resolution was carried *nem. con.* At a meeting of the Council of the Royal College of Surgeons of England, held on the 9th inst., it was resolved "that it is degrading to the profession and injurious to the public interest that Fellows or Members of the College should associate themselves with trading institutions for the treatment of disease and allow their names to be advertised in support of the practice of medicine and surgery by persons not legally qualified."

It was resolved unanimously that a marble bust of the late Sir Richard Owen, K.C.B., be obtained at a cost not exceeding 200 guineas.

A letter from Sir Ralph Thompson, K.C.B., in reference to

the arrangements for the Army Medical Examinations, was read and entered on the minutes.

The best thanks of the Council were given to Mr. W. Hunter Bailie for his present of John Hunter's consulting table.

It was proposed by Mr. Hulke, and seconded by Mr. Macnamara, and agreed to "That the Council, having learned that it is proposed, under the control of the London County Council, to open the gardens of Lincoln's Inn fields to the public, request the President and Vice-Presidents to put themselves in communication with the promoters of the Bill, with the object of securing the insertion of such conditions as they may think desirable."

Medical News.

EDINBURGH UNIVERSITY—The following gentlemen received the degrees of M.B., C.M., on Jan. 28th, 1893:

Joseph P. S. Barboza, Edinburgh (or Madras); John W. Craig, Castle Douglas; Samuel Davidson, Edinburgh; Robt. B. Gass, Durham; Geo. S. S. Hirst, Cambridge; Habeeb H. Khayatt, Assiout, Egypt; Henry C. Lloyd Melbourne, Australia; Thomas G. Macormack, Edinburgh; Ernest C. Quertier, Guernsey; George P. Richards, Herefordshire; Fred W. J. Stephenson, Blackburn, Lancashire; Arthur H. H. Vizard, Halifax, Nova Scotia.

FOOTBALL CASUALTIES—During a game at Newry, Armagh, on the 25th ult., a player fractured his leg. A young man of East Dereham has died from lockjaw, caused by injuries sustained whilst playing in a match a few days since.

MEDICAL MAGISTRATES—Dr. Henry C. March of Rochdale has been placed on the Commission of the Peace for that borough. The following gentlemen have been appointed Justices of the Peace for the county of Aberdeen:—Dr. Wm. Alexander of Tarland, Brigade-Surgeon Lieutenant-Colonel Wm. Johnston, M.D. Edin., of Newton Dee, Murtle; Dr. David Mavor of Buxburn; Dr. P. Mitchell of Old Rain, Inch; Dr. J. Reid of Dinnet; and Dr. Wm. L. Ross of Cuminstown, Monquhitter.

DR. CECCARELLI'S WILL—Of the eight hundred thousand francs (£32,000) left by the Pope's late physician, about one half has been bequeathed to the commune of Rome, to be invested and the interest devoted to the institution of beds in the hospitals of the city for the sick Roman poor. Dr. Ceccarelli, besides, has left to the hospital at Velletri his rich medical library and his splendid "armamentarium chirurgicum," comprising the instruments he himself invented. The library and "armamentarium" are valued at forty thousand francs (£1600).

OPHTHALMIA AMONG CHILDREN—At their meeting on Tuesday last the members of the Central London School District came to an important decision in respect of this subject. The success of the means adopted by the managers of the Hanwell school, founded for the treatment of ophthalmia, has induced them to receive within their partially occupied buildings children affected with the disease from any parish within the metropolitan Poor law area for a period of two years. After that time shall have expired it is expected that another body will be elected to control the management of the establishment.

THE METROPOLITAN PUBLIC GARDENS ASSOCIATION—Few public movements designed to improve the condition of the poorer classes of the metropolis are more worthy of support than that named in the heading of this paragraph. The work already accomplished by this Association is set forth in its tenth annual report, by which it will be seen that its operations have been fraught with widespread advantages to the inhabitants of the metropolis, especially to those who are compelled to live in close and, for the most part, squalid neighbourhoods. The opening of a large number of playgrounds, the improving of commons, the planting of trees in thoroughfares, the provision of seats for weary pedestrians, and the erecting of fountains for thirsty travellers have been some of the results of the labours of the Society's executive. Nothing more need be said to strengthen the appeal which the Earl of Meath has published in the newspaper press on behalf of the Association over which he presides. It should not be difficult in a wealthy city like London to raise the comparatively trifling sum (£4000) required to carry on the work which has been so successfully begun.

THE INTER-HOSPITAL FOOTBALL MATCH—In the match for the final tie for the Rugby Union Inter hospital Challenge Cup played at Richmond on Thursday, March 9th, between Guy's and St Thomas's Hospitals, the St. Thomas's team were the victors by eight points to five, thus winning the cup five years in succession. The match was very close and interesting.

MISSION TO DEEP-SEA FISHERMEN—To awaken increased interest in this movement it has been announced that a lecture will be delivered by Mr W. T. Grenfell, M.R.C.S., at the Vestry Hall, Hampstead, on Monday next, at 7 P.M. The chair will be taken by Mr Frederick Treves. The lecturer will describe the incidents connected with his recent cruise in the *Albert* Hospital Mission vessel to Newfoundland and Labrador, and the lecture which will be illustrated by lime-light views, will no doubt prove of considerable interest.

LIÈGE MEDICAL STUDENTS—The medical students of the University of Liège have formed a society for visiting patients who after their discharge from the hospital are in indigent circumstances, the students' object being to take them meat, wine and nourishing articles of diet and to supply them with creature comforts as well as to cheer them by their visits, so that convalescence may be hastened. Many charitable persons are assisting the society to obtain what is required, and a concert is being organised for its benefit with 450 performers.

FUNERAL REFORM—The Rev. Rabbi Adler took this subject for an address delivered at the monthly meeting of the Funeral Reform Association, Canon Barker presiding. The methods adopted by the lecturer and his co-religionists in consigning their dead to the grave were described, the prominent feature of such procedures being the punctilious regard to cleanliness observed by the Jews. The ancient custom was to bury in the earth without the use of coffins. No corpse was allowed to remain above ground for more than two days. No second interment was permitted in the same grave. As with all religious ceremonies amongst the Jews, the mourners at the grave-side remain covered.

THE MEDICAL SOCIETY OF LONDON—The annual dinner of the Medical Society of London was held in the Whitehall Rooms of the Hôtel Métropole on the 8th inst., Mr Hutchinson, President, being in the chair. A large number of Fellows were present and amongst the guests were several well known members of the profession in London. The feature was the appearance of the Presidents of several of the provincial medical societies. After the loyal toasts, "The Success of the Medical Society of London" was proposed by the President. At the conclusion of his speech he presented Dr Gowers with the Fothergillian Gold Medal and prize for the excellence of his contributions to medical literature, which was awarded by the vote of the Council. This is the first occasion in the history of the Society upon which this prize has been adjudicated in this manner and given as it were without competition or without the sending in of names or theses. The action of the Council was enthusiastically endorsed by the Fellows present. Dr Douglas Powell proposed the health of the incoming president, Dr Bristowe. During the course of the evening songs by Dr Frederick Roberts and Dr Samuel West were highly appreciated.

BEQUESTS AND DONATIONS TO HOSPITALS—The late Mr John Hale of Liverpool bequeathed his personal estate, amounting to between £2000 and £3000 in trust for the equal benefit of the Royal Infirmary, the Royal Southern Hospital and the Northern Hospital, Liverpool.—Mrs Phoebe S. Croker, late of Lavenham, bequeathed £100 to the Suffolk General Hospital.—Miss Mary E. Lumby, late of Halifax, bequeathed £100 to the Halifax Infirmary.—The late Miss Jane Boyd of Wallacetown, Ayr, bequeathed £100 to the Ayr County Hospital.—Mrs Frances S. Cary, late of Southampton, bequeathed £100 to the Royal South Hants Infirmary.—Mr Thomas F. Maddock, late of Chester, bequeathed £100 to the Chester Infirmary.—The late Miss M. C. Summs of Clevedon bequeathed £500 to the Royal Dispensary, Bartholomew-close, London.—The Grocers' Livery Company has made a grant of £50 to the Hospital for Epilepsy and Paralysis, Regent's Park.—The Treasurer of the Manchester Hospital for Consumption has received £500 from the executors of the late Mr James Chadwick.—The late Dr Thomas Hawksley of Chertsey bequeathed £500 to King's College Hospital, £200 to the Medical Benevolent Fund and £100 to the Medical Benevolent College at Epsom.

NOTES IN PARLIAMENT

On going into Committee of Supply on the Army Estimates Mr Lockwood has, we learn from *The Times*, expressed his intention to move for a select committee to inquire into the refusal of the Horse Guards to reinstate Mr Briggs, who resigned his commission in the army in order to be at liberty to give evidence in the Connemara case. On March 22nd, last year Mr E. Stanhope, in reply to a question in the House, expressed his opinion that Mr Briggs should not suffer loss of promotion on account of an act which he was bound to perform and stated that he would therefore be restored to the seniority he formerly held. Subsequently however a letter appeared in a Service journal giving an account of the matter which Mr Briggs held to be unfair and to which he therefore replied in the same journal. This reply appears to have been regarded by the authorities as in some way a breach of discipline and he was accordingly informed that unless he withdrew certain statements in his reply and publicly apologised, his reinstatement would not be permitted. Mr Briggs in his defence reminded the authorities that as his commission had not been gazetted he was not subject to military discipline. He added that he could not withdraw his letter as by doing so he would be practically acknowledging that the statements contained therein were untrue. He was however, willing to express his deep regret if he had unconsciously used words which might be understood as conveying unwarrantable imputations upon anyone and was ready to apologise for them. Some further correspondence has passed between Mr Briggs and the War Office but it is understood that the latter refuse to reopen the question.

The Sale of Food and Drugs

Dr Cameron has introduced a Bill to Amend the Sale of Food and Drugs Act (1875) and the Margarine Act (1857). It provides that the former Act shall apply to and include every wholesale trader or manufacturer of any article of food or drug who shall sell to the prejudice of the purchaser any article of food or drug which is not of the nature, substance and quality demanded. Another clause amends the Act of 1875 by omitting the word "written" before the words "warranty to that effect." A third deals with the mixture of chicory and coffee and a fourth defines what proportion of water in butter shall constitute adulteration.

New Hospital for Poor Sick Jews.

Sir John Kennaway asked the Under-Secretary of State for Foreign Affairs whether he would make inquiries through Her Majesty's Ambassador at Constantinople, as to the reason of the long delay in granting the firman applied for for the erection of a new hospital for poor sick Jews on the Jaffa road, outside the walls of Jerusalem, for which a site had been purchased and £5000 provided to begin the building and whether Her Majesty's Secretary of State for Foreign Affairs would move Sir Clare Ford to use his best endeavours to facilitate and expedite the granting of the firman.—Sir Edward Grey replied that this matter was receiving the attention of Her Majesty's Ambassador at Constantinople.

Glanders and Farcy in London

Mr Edward H. Bayley asked the President of the Board of Agriculture whether, in view of the alarming increase of glanders and farcy in London upwards of 2000 cases having occurred in 1893 being 90 per cent. of the cases in the country generally and the fact that glanders and farcy are contagious as regards human beings as well as horses, he would take measures to stamp out the disease by means of a system of inspection of stables and compulsory slaughter of infected horses, with or without compensation of owners.—Mr Herbert Gardner, in reply referred to the order he issued recently and intimated that the number of outbreaks recorded since the commencement of the present year was less than in the corresponding period of 1892. There was no cause whatever for alarm on the subject, but he was carefully watching the operation of the new order with a view to determine whether any further action on his part was necessary.

Small-pox and Vaccination.

In reply to a question put by Mr Hopwood Mr Campbell Bannerman stated that five militiamen at Halifax were attacked with small pox and were removed to civil hospitals and the troops were confined to barracks for three days. None of the men attacked had been revaccinated. He had been advised by the medical authorities that vaccination and revaccination acted as a sure prevention to small pox but he did not regard himself as an authority on the matter. The subject was also referred to on the 3rd inst., when, in reply to another question by Mr Hopwood Sir Walter Foster said he had been informed by the guardians of the Wigton Union that a fatal case of small pox had occurred at the workhouse on Feb 3rd, and that the medical officer deemed it necessary under the circumstances that a child who occupied a ward close to that in which the small pox patient had died should be vaccinated. The mother however objected, but the operation was ordered by the guardians to be performed. In the opinion of the Local Government Board it was not legal for the

children of inmates of a workhouse to be submitted to vaccination if the parents objected

Hemp Drugs in Bengal.

On this subject Mr. Caine put a question to Mr. G. Russell, who said that the Secretary of State had proposed to request the Viceroy to appoint a Commission to inquire into the cultivation and trade in hemp drugs and would be glad if the result of the inquiry would be to show that further restrictions could be placed upon the sale and consumption of those drugs. Instructions would be given to ensure that the inquiry by the Commission, which would be composed in part of non-official natives of India, should be as complete as possible, but the methods of procedure were to be left to the discretion of the Commission. Mr. G. Russell moreover, stated, in reply to another question put to him that it was not contemplated that the Commission should deal with the opium question.

Cholera Hospitals (Ireland) Bill.

Mr. J. Morley introduced a Bill to enable sanitary authorities in Ireland to take possession of land for the erection of temporary cholera hospitals. The Bill was subsequently read a second time.

Medical Officers and Public Bodies.

On the 3rd inst. in answer to Mr. Weir, Mr. Shaw Lefevre said he had been wrongly reported in the press as having come to an adverse opinion on the subject of the ventilation of the House of Commons. In consequence of the recommendations of the Committee appointed for the purpose great improvements had already been effected.

Dresden Sanitary Conference.

On the 6th inst. Sir E. Grey stated in reply to a question put by Mr. J. W. Lowther that Her Majesty's Government had consented to take part in the Dresden Conference which was expected to meet on the 11th inst. The British representatives would be Mr. Strachey, the Minister Resident at Dresden, and Dr. Thorne Thorne of the Local Government Board, assisted by Mr. Farnall of the Foreign Office.

The Health of our Troops in India.

Mr. G. Russell, in answer to a question by Mr. Caine, said that the rate of admissions to hospital from venereal diseases per 1000 of strength in 1890 (the last year for which complete statistics had been received) was—British troops, 503.5, native troops 41.1.

Tuberculosis.

On the 7th inst. Mr. W. Whitelaw asked for the number of cases of tuberculosis in home-bred cattle whose carcases were condemned last year on account of tuberculosis. Mr. G. A. Innes expressed his inability to supply the information asked for.

Pleuro-Pneumonia.

Mr. Maartney called attention to the subject of the introduction of this disease into the United Kingdom by the importation of foreign cattle, and moved a resolution to the effect that no foreign animal, with certain exceptions, having been allowed to be landed, should be suffered to leave the wharf alive. The resolution was discussed at considerable length. The Solicitor General pointed out that if the stipulation of the Act of 1873 were reasonably satisfied no danger of such importation would arise. Mr. Gardner said the resolution was opposed to the general principle of free trade and he hoped the House would reject it. Mr. Chaplin supported the resolution. He said we had now arrived within a measurable distance of being quite free from pleuro-pneumonia in the future, but in order to attain this object it was essential that all animals arriving in this country should be immediately slaughtered. The resolution was rejected by a majority of 180 against 151.

Public Health.

On the 8th inst. Sir H. Roscoe brought in a Bill to amend and extend the Public Health (London) Act, 1891.

The Sanitary Condition of Thames Tugs.

Mr. Havelock Wilson asked the President of the Local Government Board whether he was aware that the medical officer of the port of London had declared that in many cases the tug boats on the River Thames were in an insanitary condition, particularly with regard to the source of drinking water which was taken from the river and which he described as a most dangerous proceeding, and what steps could be taken to prevent the development of disease among the floating population through this practice. Mr. Fowler replied that he had communicated with the Medical Officer of the Port of London on the subject of this question and he informed him that there was some foundation for the report as to the insanitary condition of some of the steam tugs on the Upper Thames, although it could not be said that generally they were in a bad state. He was making a close and careful inspection of these tugs and was requiring that defects should be remedied. In the case of any tug where it was known that water had been obtained from the river, the medical officer insisted upon the emptying of the water vessels and after warning the master of the tug as to the danger communicated with the owners with the view to such instructions being given as would prevent the use for drinking purposes of water taken direct from the river.

The Proposed Fever Hospital at Tooting.

Mr. Fowler in reply to a question put by Mr. Kimber, informed him that the experienced inspectors who conducted the inquiry as to the proposed fever hospital acted in accordance with the practice of the Local Government Board and he saw no reason for interfering with their discretion. The inquiry was limited to the proposal to acquire a specified site and such an inquiry could not properly have been extended to other sites in respect of which there was no proposal of the Managers of the Metropolitan Asylum District before the Local Government Board and with regard to which no notice had been given to those interested in the localities where the sites were situated. Any information that could be given as to sites which were available for hospital purposes, and which were considered to be more suitable than the site in question, should be submitted in the first instance to the Asylum Managers and he should be prepared to receive and consider a copy of any communication which might be addressed to the Managers on the subject.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 8 o'clock on the Thursday morning of each week for publication in the next number.

ALLOTT, JAS. H. L. M.B. CM. Edin., has been appointed Honorary Surgeon to the Beckett Hospital and Dispensary, Barnsley.
BLACKHAM, ROBERT J., L.R.C.P., L.R.C.S.E., L.F.P.S. Glasg., L.M. (Rotunda Faculty), has been appointed Physician to the Sidcup Hospital, London S.E.
BLAKISTON, A. A., M.R.C.S., has been reappointed Medical Officer of Health for the Borough of Glastonbury.
BROWN, STANLEY M., M.R.C.S., L.R.C.P. Lond., has been appointed Junior House Surgeon to the Salford Royal Hospital, vice Newby, appointed House Surgeon.
BURNETT, J. E., M.B., CM. Edin., M.R.C.S., has been appointed House Physician to the Hospital for Consumption and Diseases of the Chest, Brompton.
CALLAGHAN, THOS., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed an extern Physician to the Cork Fever Hospital.
COPPE, F. B., L.R.C.P., L.M., L.R.C.S. Irel., has been appointed Medical Officer to the Dublin Commercial Medical Aid Association.
COLMER, P. A., L.S.A., has been appointed Honorary Medical Officer to the Yeovil District Hospital, vice Garland, resigned.
DOVELAN, JOHN O'CONNOR, Lic. & L.M. R.C.S. & R.C.P. Irel., M.P.C., has been appointed Assistant Medical Officer to the Richmond District Lunatic Asylum, Dublin.
DUNCAN, R. B., M.B., B.S. Durh., has been appointed Visiting Medical Assistant to the Newcastle-on-Tyne Dispensary.
GILES, ARTHUR E., M.D., B.Sc. Lond., M.B. Ch.B. Vict., M.R.C.P., M.R.C.S., has been appointed Physician Accoucheur to the St. Pancras and Northern Dispensary, Euston road, N.W.
HASLAM, W. ARTHUR, L.R.C.P. Lond., M.R.C.S., has been appointed Junior House Surgeon to the London Temperance Hospital, Hampstead road.
HINE, ALFRED, ERNEST, M.R.C.S., L.R.C.P. Lond., has been appointed Resident Obstetrical Officer to the Charing-cross Hospital.
HUNTER, W. L., M.D. Dub., B.Ch., D.P.H. Eng., has been reappointed Medical Officer for the Third Sanitary District of the North Derbyshire Union.
KARKEK, P. C., M.R.C.S., has been reappointed Medical Officer of Health for St. Marychurch, Torquay.
MENZIES, JAS., L.R.C.P., L.M., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer of Health to the Shireoaks Sick Club, Worksop.
MOORE, SAMSON G., M.B., B.S. Victoria Univ., has been appointed Assistant Port Sanitary Medical Officer, Liverpool.
NEWBY, GERVAISE E., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to the Salford Royal Hospital, vice Heywood, resigned.
PRATT, JOHN W., L.R.C.P., L.M. Edin., M.R.C.S., has been reappointed Medical Officer of Health for the Wellescombe Urban Sanitary District of the Wellington Union.
RAW, NATHAN M.D., B.S. L.S. Sc., Senior House Surgeon, Bolton Infirmary, has been appointed Medical Superintendent of the Dundee Royal Infirmary, vice M. Coak, resigned.
RICE, B. M.D. Lond., M.R.C.S., has been appointed Police Surgeon for the Borough of Leamington.
SAYAGE, THOMAS M.D., M.R.C.P. Lond., F.R.C.S. Eng., has been appointed Professor of Gynecology in Mason College, Birmingham, vice Tait, resigned.
SEGUNDO, CHAS. SEMPILL DE, L.R.C.P. Lond., M.R.C.S., has been appointed House Surgeon to the London Temperance Hospital, Hampstead road.
TAILOR, JAMES M.A. Edin., M.B. MD., M.R.C.P. Lond., has been appointed Assistant Physician at Queen's Square Hospital.
WEBB, C. F. M.D. Durh., F.R.C.S. FRCP. Edin., M.R.C.S., has been reappointed Medical Officer of Health for the First Sanitary District of the Basingstoke Union.
YOUNG, E. H., M.D. Durh., L.R.C.P. Lond., M.R.C.S., D.P.H., has been reappointed Medical Officer of Health for the Oakhampton Rural and Urban Sanitary Districts.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BLACKBURY AND EAST LANCASHIRE INFIRMARY.—Junior House Surgeon. Salary £50 per annum with board, lodging, washing &c.
BOARD OF WORKS for the POPLAR DISTRICT.—Medical Officer of Health for the Poplar and Bromley parishes. Salary £400 per annum. Apply to the Clerk to the Board of Officers, 117 High street, Poplar.
CANCER HOSPITAL (FREE) Fulham road S.W.—House Surgeon for six months. Salary at the rate of £50 per annum, with board and residence.
DENTAL HOSPITAL OF LONDON, Leicester square.—Assistant Anaesthetist.
EVELINA HOSPITAL FOR SICK CHILDREN, Southwark bridge-road, S.E.—Surgeon to Out-patients.
FARRINGTON GENERAL DISPENSARY, Bartlett's buildings, Holborn circus, E.C.—Surgeon.
GENERAL HOSPITAL, Birmingham.—Assistant Surgeon for three years. Honorarium £100 per annum.
GENERAL HOSPITAL, Birmingham.—Pathologist (non resident). Salary £120 per annum.

GENERAL HOSPITAL, Birmingham—Assistant House Surgeon for six months Residence, board and washing provided
HARTLEPOOL HOSPITAL—House Surgeon Salary £60 per annum with board, lodging and washing
LIVERPOOL ROYAL INFIRMARY—Honorary Laryngologist and Honorary Dermatologist
LONDON COUNTY ASYLUM, Claybury Woodford, Essex—Second Assistant Medical Officer Salary £180 per annum rising £10 a year to £230 with board lodging and washing Apply to the Clerk to the Asylums Committee Office 21, Whitehall place S W

partment 9 15 A.M.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office

Lectures, original articles, and reports should be written on one side only of the paper

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor"

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Publisher"

We cannot undertake to return MSS not used

THE POWER OF THE CORONER AND POST MORTEM EXAMINATIONS

A CORONER, at a recent inquest at Newnham on Severn, expressed him self very strongly in respect of the husband of the deceased having refused to permit a post-mortem examination which he had ordered. He sympathised with the husband, but intimated that if he persisted he would have to send him to gaol. The poor man immediately saw his error, and said he had no intention of defying the law

L.D.S.—The question whether a dental surgeon by virtue of his licentiate-ship has a right to administer nitrous oxide gas has not yet been thoroughly determined. In case of a death of course a coroner's inquest would have to be held. In the case of an unqualified though registered, dentist his position is very different and far graver than that of the L.D.S. We do not hesitate for a moment in saying that no person other than a registered medical practitioner ought to administer any of the more dangerous anesthetics—such as ether, chloroform &c.—and by so doing he places himself in an unenviable position

THE PREMIER ON MEDICAL FEES

To the Editors of THE LANCET

SIRS,—It must be a comfort to the medical profession to discover that you have lost no time in drawing attention to Mr Gladstone's statement—or, rather misstatement—with regard to the increase of medical fees. It is both curious and unfortunate that the Premier who is justly regarded as little short of a talking encyclopedia, and whose utterances gain European notoriety, should have fallen into an error of this description the time having long since arrived when a reaction is so necessary in the public mind to remove the fallacious ideas in respect to medical charges. The general public have to be reminded that the majority of medical men are not by inheritance millionaires nor are they likely to acquire such a status by supplying advice and medicine at sixpence which in the aggregate appears to represent the majority of fees and it is not impossible that Mr Gladstone was confounding quantity with quality when he referred to the increase thereof. And no doubt in the former sense he would be correct seeing that it has become a common practice for a single practitioner to run two or three establishments, which after all represent so many hybrid shops, in order to realise a so-called income, and which is equivalent to saying that men of the present day have to engage in three times the amount of practice to secure an income which could be obtained with relative ease in a past generation. What an ex-Chancellor of the Exchequer whose financial intellect has accustomed itself to regulate the purse-strings of the British Empire would think of 'advice and medicine for sixpence' it is not easy to know but, speaking as a humble practitioner, I have no hesitation in expressing an opinion that he who gives advice and medicine for sixpence pitiable as his condition may be nevertheless has a much greater advantage than he who takes 1*l.* and of such an one it may literally be said that "it is more blessed to give than receive"—I am Sirs yours faithfully,
SIXPENCE.
London, March 6th, 1893.

MEDICAL ETHICS AT BURTON

THE following circular has been forwarded to us —

"181, Horninglow street, Burton-on-Trent November 1871.

"I have the pleasure to inform you that, having resigned my position as Senior Surgeon to the Friendly Societies Association I am now carrying on my profession as physician and surgeon at the above address. The prescription, case and other books used in the practice carried on for so many years by Messrs. R. S. and (late) Paul Belcher have, with the nucleus of their practice been transferred to me—I am, yours obediently,

'JOHN OLDERSHAW,

'Member of the Royal College of Physicians Physician and Licentiate in Medicine Diplomate in State Medicine Certificate in Sanitary Science Licentiate of Royal College of Physicians Edinburgh Licentiate of Royal College of Surgeons, Edinburgh, Licentiate of Faculty of Physicians and Surgeons Glasgow Licentiate in Midwifery and Diseases of Women King and Queens College (by examination) Late Assistant Clinical Physician to Royal Infirmary, Liverpool Surgeon to the Dispensary for Diseases of Women and Children, Liverpool.

Mr Henry Morris—Our correspondent should consult the columns of *Le Progrès Médical*—Le Numéro des Étudiants, Nov 5th 1902.

"THE UNITED STATES AS A FIELD OF PRACTICE"

To the Editors of THE LANCET

SIRS,—Now and again one sees in the columns of THE LANCET the question asked as to what are the chances of obtaining a practice in the United States. "Viajaro" is the most recent inquirer, and I observe in your issue of Feb 11th a response (if a response it can be called) by "Yale University" To state that "there is always room at the top" is, I imagine, scarcely the kind of information "Viajaro" would like to receive. Most people (and they need not be very astute ones at that) are aware that merit sooner or later asserts itself in all countries the United States included. But I think 'Yale University' will concede after all, that America is the quack's El Dorado and that competing with quacks is neither dignified nor remunerative. As a rule the quack will get the better of the struggle, for he will descend to methods that an honourable and conscientious member of the profession can neither countenance nor practise. I agree with 'Yale University' that the newly arrived addition to our ranks will be dubbed "Doctor," "whatever his diploma" but at the same time I may as well remind "Viajaro" that the title of Doctor is a very cheap one in this country and that it is applied to common farriers, patent medicine pedlars and a host of druggists. The ratio of legitimate practitioners to the population in the States is 1 to 500, and this does not include the great number of humbugs that flood the country. Counter prescribing by druggists is very extensively practised, and there is a great deal of 'self doctoring' carried on by the average American. I seldom see a patient who has not been administering this or that nostrum to himself before sending for me. To give an idea of the enormous sale of patent medicine in this country, I may state that from one third to one half of the space of the average chemist's shop is allotted to these remedies and that they are for sale at every grocery. There is comparatively little dispensing done by doctors, but undoubtedly for self protection the doctor will have to do more of it, and the feeling among practitioners is growing rapidly in favour of reviving this old custom. The fees are fair and, generally speaking doctors charges are made upon the principle of getting as much as you can, but it must be remembered that a doctor here considers he does extraordinarily well if he collects two thirds of his accounts. If patients do not wish to pay it is seldom that they can be compelled to do so. Poverty is very much on the increase in the United States and charitable institutions likewise. 'Viajaro' if he is bent on emigration, had better betake himself to a British colony, where things are fashioned after the mother country. The last man desiring to emigrate to the United States ought to be the medical practitioner

I am, Sirs, yours faithfully

A BRITISH PRACTITIONER TWENTY YEARS
RESIDENT IN THE STATES.

February 1893.

AMENITIES BETWEEN MEDICAL MEN

THE rule by which medical men beset other practitioners and their families is a very good one and should be well observed. We are asked if it is in accordance with medical etiquette if, when a medical man takes his brother to a consultant, the consultant is to charge the full fee, the medical men both having been fellow students of the same hospital, and the brothers being sons of a medical man. It seems to us that the answer would depend much on the means of the lay brother. The consultant should not be deprived of his fee if the patient was well able to pay although he did happen to be brother and son to medical men. A good rule should not be strained in its application. On the other hand, the consultant in such cases generally contrives to ascertain the facts and to act considerably

'INSOLUBLE TABLOIDS.'

To the Editors of THE LANCET

SIRS—I am much obliged for your insertion of my letter on the above subject. There is however a mistake in the letter probably owing to my rather illegible writing which makes it read badly "Data of motion" should be date of insertion.—Yours truly,
March 7th, 1893.
WILLIAM G GROVES.

TESTING THE VIRULENCE OF CHOLERA BACILLI.

THE experiment of Professor Pettenkofer, designed to test the virulence of the comma bacilli, has been repeated by Dr Hasterlik and three other physicians at the Pathological Institute, Vienna. The cultures used were derived partly from German and partly from Buda Pest cases of cholera, and the quantity of culture employed in each case was one cubic centimetre. In two experiments 100 grammes of 1 per cent. solution of bicarbonate of soda were taken before swallowing the culture with the design of neutralising the acidity of the stomach. In two of the experiments only one of the six was diarrhoea observed, and that merely in a slight form whilst in the remaining three no effect whatever was produced. The defecations were examined microscopically and revealed the presence of bacilli.

MD—Each particular agreement must be dealt with on its own merits, according to the wording of the document and attendant circumstances. The "prevalent opinion suggested by our correspondent is not, we think, well founded

"A TOO INDESTRUCTIBLE BANDAGE"—(AN IRON RING USED AS A TRUSS.)

To the Editors of THE LANCET.

SIRS—In your issue of Feb 25th was recorded the case, related in a Spanish medical journal, of a man who applied an iron ring around his external genitals to keep up some dressings about his groins. In 1877 a somewhat similar case was treated at the old South Devon and East Cornwall Hospital here. A fisherman who had an inguinal hernia broke his truss whilst at sea and fearing that the rupture would descend into the scrotum he passed with some difficulty a wrought iron ring over his external genitalia. For one day all went well and the ring formed an admirable and efficient truss but he then unfortunately struck his scrotum against the gunwale of his boat and the parts swelled very rapidly. A few days afterwards, on admission into hospital his scrotum and penis were found to be enormously swollen and oedematous. It was at once evident that the only means of relieving the patient's condition was by cutting through the ring with a file. The parts were first incised to relieve the oedema. I cannot remember how many hours it took us to cut through the ring, but it was a very arduous task for us and a very painful ordeal for the patient. There was afterwards considerable sloughing, but eventually a good recovery was made, and the patient was discharged with a well fitting truss. The ring was half an inch thick and the file was used obliquely.

I am Sirs, yours faithfully

J ELLIOT SQUARE, F.R.C.S.

Plymouth, March, 1893.

MEDICAL ADVERTISEMENTS AT THE EAST END OF LONDON

A GENERAL PRACTITIONER sends us specimens of two bills which had been left at the houses of his patients one issued by a medical graduate—Dr Wallace M.B. C.M., 325, Old Ford road—from whom better things might have been expected. Medicine and advice are offered for 6d., and midwifery and diseases of women are boasted of as a specialty, but the fee for midwifery is from 10s. 6d. The other bill advertises the Roman road Provident Dispensary and Drug Stores 224 Roman road. Proprietor, Dr Taynton resident medical officer, Dr Wilson.

GINDERS FUND

To the Editors of THE LANCET.

SIRS—As the result of the appeal on behalf of the widow of the late A. Gerard Ginders L.R.C.P. Edin., who went down in the ill fated *Roumania* the following sums have been received—

THE LANCET Relief Fund	£25 0 0
British Medical Benevolent Fund	10 0 0
Donations	60 0 0
Total	£95 0 0

The committee consider the sum inadequate for the purpose they have in view—namely the furnishing a house for Mrs Ginders to take in lodgers—and would earnestly appeal for further contributions. Remittances to be sent to Dr Quintin McLennan, 191, Pitt-street, Glasgow

I am Sirs, yours faithfully,

HENRY E CLARK
(Convener of Committee).

Glasgow March 7th 1893.

TAKING THE AIR."

To the Editors of THE LANCET.

SIRS—There is in many towns among the poorer class of invalids a great want of some cheap mode of "taking the air." The donkey or bath-chair are perforce well enough for the helpless and unwieldy but they are uncomfortable too invalid like and too expensive for the ordinary convalescent for the phthisical or the anemic &c. for whom fresh air and sunlight are so essential. I would therefore suggest that the rickshaw "so much used and valued abroad might be introduced with great advantage to both the public and the unemployed. With a pneumatic tyre and a moderate charge its success would be assured and the cycle depots would find their wear and tear infinitesimal and damage to them nil if added to their stock.

I remain, Sirs yours faithfully

March 1893.

LD

THE RIGHT OF AN APOTHECARY TO CALL HIMSELF SURGEON

A CORRESPONDENT objects much to an apothecary who has recently settled near him and taken a chemist's shop calling himself "surgeon." He does not say what is the date of the licence. A apothecary under the Act of 1856 is qualified in surgery as well as in medicine, and is to all intents and purposes a surgeon. If the licence dates further back to a time when it did not involve qualification in surgery the use of the title is illegal. We should scarcely advise our correspondent to "take any action" in the matter. The licentiate is on the Register we presume, and the limitation of his licence if it be limited will perhaps appear one day in the county court if he attempts to recover charges in a surgical case.

Dr F Evans (Cardiff)—The condition would most probably prove a disqualification but the Military Secretary Horse Guards, might be officially applied to

TABLOIDS

To the Editors of THE LANCET

SIRS—Permit me through the columns of THE LANCET to suggest a method of employing hypodermic tabloids which I have practised for the last year. By simply placing them under the tongue I find that they are so quickly absorbed that their full physiological effect is as quickly produced as by subcutaneous injection. Since I discovered this mode I have seldom needed to resort to the syringe the simpler plan having invariably proved equally reliable. The only objection is the taste, and I have written to some well known makers with a view to remedying this defect. Even as now made I am quite convinced that the simplicity and efficacy of this method will secure for it a wide adoption.

I am Sirs yours truly,

Loughborough March 7th, 1893 WM PAULSON, L.R.C.P. Lond.

CAN MEDICAL PRACTITIONERS VEND THEIR PRESCRIPTIONS AS PATENT MEDICINES?

WHEN a medical man sells his prescriptions in a commercial way to capitalists or uses them for creating patent and secret remedies, to be advertised and turned to commercial account for his benefit, he abandons all professional paths, and must not be surprised if, on proof being given, the medical authorities of the profession withdraw his diploma or his registration. He would have no right of complaint, for in so acting he would proclaim that he had ceased to rely on professional methods of success, and had adopted others inconsistent with the retention of his professional position.

A B—Our correspondent may justly complain of the terms of the letter he received in explanation. They are not courteous and not such as the busiest man is justified in writing to an applicant for an assistantship

THE "MEDICAL DIRECTORY"

To the Editors of THE LANCET

SIRS—I have to spare a set of Churchill's "Medical Directory" complete since 1847 (first and second vols. 1845 and 1840, missing) which I should be very glad to give to any medical library wanting them if you could make the fact known. I am Sirs, yours truly

Birmingham March, 1893

LAWSON TAIT

THE Prudential Assurance Company Limited, has issued a report and accounts for the year 1892 which disclose an unprecedentedly large measure of success, and justify it by the discovery of a very high standard of efficiency and economy in the management of the enormous business transacted by the company. Henceforth an annual valuation will take the place of the quinquennial operation which has heretofore sufficed, and the change is inaugurated by a valuation report now submitted, together with a customary report upon the business of the year. The very favourable criticism which we have felt at liberty to pass upon the one may be extended to the other of these statements.

THE following card has been sent to us—

"Dr Walter (of 87, Noel-street) attends at S Cook's Dispensing Chemist, 76 Radford road, Hyacinth green, from 3 to 4 P.M. daily (Thursday excepted). Private consulting room."

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received—*Arms and Explosives Court Journal* Lyttelton Times (New Zealand) West Hain Herald, Port Elizabeth Telegraph (Cape of Good Hope) The Weekly Press (Pretoria) The Cambrian (Swansea) The Morning Reford Workshop and Gainsborough News Manx Sun (Douglas Isle of Man) Fulham and West London Observer Western Chronicle South Wales Echo Hampshire Advertiser, Eastbourne Standard Devon Gazette Democrat (Boston, Mass.) Groonian Lecture

THE POSITION OF PATHOLOGY AMONG THE BIOLOGICAL SCIENCES.

Delivered before the Royal Society on Thursday, March 16th, 1893,

BY PROFESSOR RUDOLF VIRCHOW,
FOREIGN MEMBER OF THE ROYAL SOCIETY

GENTLEMEN,—It is now nearly ten years since this illustrious Society conferred on me the unexpected honour of electing me one of its Foreign Members. Not alone this, but last autumn it deemed me worthy of a further honour, in awarding me the Copley Medal—a token of the highest recognition of my work, the significance of which far exceeds the distinctions which the changing favour of political powers is accustomed to bestow. Nevertheless, deeply as I appreciated this mark of its constant and increasing esteem, still I was not in a position to offer my thanks personally to the Society. Numerous duties, official and private, the weight of which has increased with each year, compelled me to work continuously at home, and the extension of international relations becoming more intimate, has for a long time restricted the freedom of my movements even during the vacations. With great indulgence, which I fully know how to appreciate, the Council has allowed me to postpone the date of my appearance in its midst. Hence you see me only to-day amongst you, and I may tell you in person how very grateful I am to this Society, and how great an incentive to new efforts your recognition has become to me.

Who of us is not in need of friendly encouragement in the changing events of life? True, happiness is not based on the appreciation of others, but on the consciousness of one's own honest labour. How otherwise should we hold our ground in the midst of the turmoil of the day? How should we preserve the hope of progress and of final victory against the attacks of opponents and the insults which are spared to no one who comes before the public? He who during a long and busy life is exposed to public opinion certainly learns to bear unjust criticism with equanimity, but this comes only through the confidence that our cause is the best, and that some day it must triumph. Such is our hope in our wrestlings for progress in science and art. Such is our hope in our struggles for civil and religious liberty, and in this hope we gradually become hardened against malicious attacks. It is a kind of immunisation which, I acknowledge, has also great drawbacks for this hardening against unjust attacks leads very easily to a similar indifference towards just attacks, and, owing to the tendency to contradiction rooted in the nature of human thought, it finally leads also to indifference to praise and recognition. One withdraws again and again into oneself, discontented with the world and with oneself also, but who can so completely retire within himself that the consciousness of the insufficiency of human thought, and that the criticisms of opponents are justified, cannot break through the crust of even the most hardened self-consciousness? Happy is he who has courage enough to keep up or regain his connexions with other men, and to take part in the common work. Thrice happy he who does not lack in this work the flattering commendation of esteemed colleagues. Such were the thoughts which filled my mind as, looking forward to the present occasion, I reviewed my own life and the history of science, or to use another expression, the fortunes of our predecessors. How often have I found myself in a state of despondency with a feeling of depression. And the history of science—what long periods of stagnation and numerous interruptions has it not experienced owing to the victory of erroneous doctrines. What has saved me is the habit of work, which has not forsaken me even in the days of outward misfortune—that habit of scientific work which has always appeared to me as a recreation, even after wearying and useless efforts in political, social and religious matters. That which has saved science is identically the same, it only appears to be different, because the coöperation of many is necessary to secure the advance of science, hence, the exalting and consoling thought that one nation after another comes to the front to take its share in the work. When the star of science becomes dim in one nation it rises sooner or later to yet

brighter glory in another, and thus one nation after another becomes the teacher of the world. No science more often than medicine has gone through these waxings and wanings of brilliancy, for medicine alone of all the sciences has, for more than 2000 years found ever-new homes in the course of a progress which, though often disturbed, has never been wholly arrested. It would lead us too far to illustrate this with examples drawn from the entire past. It is enough for my present purpose to take the outlines of modern medicine as the object of our consideration. Such a sketch, cursory as it must be, ought at the same time to throw some light on the intellectual relations of both nations, English and German, for these have taken a prominent part in establishing the principles of modern medicine. The downfall of the old medicine, the so-called humoral pathology, was brought about in the beginning of the sixteenth century. We in Germany are inclined to attribute to our nation a decisive rôle in this memorable struggle. It was a man of our race, Andreas Vesalius, of Wesel, who transformed anatomy into an exact science, and who thus at one stroke created for medicine a solid foundation, which it has retained ever since and, let us hope, will never again lose. But the principal blow to the old medicine was struck by his somewhat older contemporary, Paracelsus that charlatan, yet gifted physician, who removed from amongst the beliefs of mankind the doctrine of the four humours, which, quasi chemical in its construction, formed the basis of the old pathology. Strangely enough, he accomplished this with weapons borrowed from the armoury of the Arabs, the successors of the Greeks and the chief representatives of the mediæval humoral pathology. From them also he borrowed alchemy and, at the same time, the fantastic spiritualism of the East, which found a clear expression in his doctrine of the "archæus," as the determining force in all living beings.

In this way the new medicine, at its very birth, absorbed the germs of that ruinous contradiction which, even up to this present century, has kept up the embittered strife of the schools. To Vesalius is due the exact tendency which arises from the observation of actual conditions, and which, without going further we may call the anatomical. Paracelsus who pronounced the anatomy of the dead body to be useless and sought for the basis of life as the highest goal of knowledge, demanded "contemplation" before all else, and, just as he himself arrived in this way at the metaphysical construction of the archæus, so he unchained among his followers a wild and absolutely fruitless mysticism. Nevertheless there lay hidden in that "contemplation" of his, a healthy kernel which would not allow the intellectual activity which it had stirred up to come to rest. It was the idea of life which formed the ultimate problem for all future research. Strangely enough, this idea, which always existed in the popular mind and which is in an unmistakable form present even amongst primitive nations, had been driven far into the background in scholastic medicine. Ever since the time of Hippocrates it had been the custom to use, instead of life, the obscure expression "φύσις," *natura*, but in vain does one seek for a more exact definition of the term. To Paracelsus nature was living and the basis of his life was that very "archæus," a force differing from matter, and separable from it, or, as he himself expressed it in the sense of the Arabs, a spirit, *spiritus*. In the compound organism man,—the *mikrokosmos*,—each part, according to him, had its own "archæus," but the whole was ruled by the "archæus maximus" the "spiritus rector." From this premiss has proceeded the long succession of vitalistic schools which, in ever changing forms, and with ever new nomenclature, introduced into the notions of physicians this idea of a fundamental principle of life.

If the sagacious Georg Ernst Stahl, whose services to the development of chemistry are now acknowledged everywhere, substituted the soul for the "spiritus rector" and so created a system of animism, the last vestiges of which have disappeared from the school of Montpellier within our own time only so also in turn did the pure vitalists build up on the dogma of specific dynamic energies maintained so stoutly by the physicists that notion of the vital force the half spiritualistic and half physical character of which has contributed so much even in our day to puzzle and mislead men's minds. The doctrine of the vital force found its strongest support in the "Naturphilosophie," especially in that which on German ground, soon obtained universal sovereignty. This summary exposition of mine has greatly anticipated the historical progress of the evolution of medicine. It is now time to pay proper homage to the great investigator who

from his school days in Leyden to his professorship in Göttingen. It was in this sense that he understood the irritability of the muscles, and in the same sense he denied this property to the nerves. This dispute about the irritability of muscles has continued far into the present century, its long duration becomes intelligible only when we bear in mind that, without the most exact knowledge of its historical development, even the very statement of the question is liable to be misunderstood.

As a matter of fact, so far as we know, the nerves are not contractile like the muscles on the other hand, the muscles are not only contractile, but are also irritable. Irritability and contractility are not identical, even when they occur in the same part. The nerve current, on the other hand, cannot be compared with the blood stream, it does not consist in the movement of a fluid, but is of electrical nature, and hence there is no need for its production of a contraction of the nerve-tubes. It was also an erroneous conclusion that every irritated part contracts. Instead of contraction, secretion, or, under certain circumstances, a more vigorous nutrition, may occur as the final result of irritation. Hence we use a more comprehensive term in order to express this final result, and call all forms of it "actions." While Glisson defined all "*actio propria sic dicta*" as "*motus activus*," we distinguish different kinds according to the nature of the effects, or, expressed otherwise, according to the direction of the activity (nutrition, formation and function), but we agree with the above thinker in the opinion that no vital energy is ever set free without stimulus, that therefore every action is of an irritable nature. In this irritation, according to my idea, consists the "*principium dividendi*," according to which we must distinguish between active and passive processes of life, and in this way we gain also a basis for the fundamental division of pathological elementary processes. How much work has been necessary in order to render this conception possible. And how great, even now, is the number of our colleagues who have not fully accepted it. The reason for this difficulty is twofold. Most of the vital actions of life, whenever they manifest themselves by visible events, are of a compound nature. As a rule very various, at times wholly unlike parts, each with its specific energy, combine to produce them. Not infrequently it thereby happens that in the visible sum of final effects one part behaves in an active, the other in a passive manner. It is only the most minute analysis of the phenomenon, tracing it right back to the elementary parts, which allows the total result to be resolved into its components, such an analysis cannot for the most part be expressed in current language except at great length. No language in the world is rich enough to possess special expressions for each such combination. Only too often we help ourselves out of the difficulty by regarding the compound phenomenon as a simple one, and by expressing its character according to some chief trait which stands out in a commanding manner from the general picture. This is the practical difficulty. With it, however a theoretical difficulty is very often combined. The human mind, owing to a natural impulse, seeks in the phenomena indications of their determining cause. The more complex the phenomenon the more busy is the imagination in order to convert it into a simple one and to find a unitarian cause for it. So has it happened in respect to life, so in respect to disease. The course of thought followed by Glisson is opposed to such an explanation. He had no scruple in dividing the unit of life into a large number of individual lives. Although the knowledge we now possess of the arrangements of the body was absolutely foreign to him, yet he arrived quite logically at the *vita propria*, the proper elementary life, of the several parts. To be sure, this expression, as far as I can see is not to be found in his works, but occurs first in those of Gaubius, but Glisson says distinctly: "*Quod vivit per se, vivit vitam a nulla creatura præter se ipsum dependentem. Hoc enim verba vivere per se sonant.*" The unitarian efforts of the following period relentlessly passed over the tendency of which I have just spoken. Some returned to the old Mosaic dictum, "*the life of the body is in the blood*," others gave the nervous system and the brain especially, the first place in their consideration. Thus once more was renewed the old struggle which for thousands of years had divided the schools of medicine into humoral and solidar pathology. Even when we ourselves entered on scientific work, hæmatopathologists stood in hostile attitude to neuro-pathologists. In England humoral pathology found a strong support in the

great and legitimate authority of John Hunter. Although this distinguished practitioner never shared the one-sidedness of the later pathologists, but rather attributed to the solid parts the living principle—the existence of which he assumed—nevertheless, in his investigations, the blood took precedence over all other parts as the chief vehicle of life.

One must, however, recall to mind that Hunter laid special stress on the fact that life and organisation are not bound to each other, since animal substances which are not organised can possess life. He started, as has already been noticed, from the erroneous conception that eggs are *not* organised, and that it was not till after incubation that the first act of organisation—namely, the formation of vessels—took place. He considered his "*diffuse matter*" ("*materna vita diffusa*") as the actual carrier of life, and this was to be met with not only in the solid parts, but in the blood also. This matter, according to him, existed in the brain in a remarkable degree of concentration, but its presence was quite independent of all nervous structures, as is shown by the example of the lower animals which possess no nerves. In the posthumous writings of Hunter, which Owen has collected, the very striking expression "*simple life*" is met with, a state most clearly to be recognised in plants and the lowest animals. This simple life was in Hunter's view the ultimate source of all living actions, pathological as well as physiological. Hunter was out and out a vitalist, but his materialistic vitalism, so to speak, differed *toto calo* from the dynamic vitalism of the German schools. If living matter existed independently of all organisation, such living matter was beyond the scope of anatomical investigation, but, on the other hand, if it were present in non-organised parts, such as an egg, it was in itself the ultimate source of the organisation which subsequently makes its appearance in these parts. It must, therefore, to adopt a later mode of expression, be of a plastic nature. Here Hunter's notion agreed with that of the plastic lymph, as developed by Hewson, and it was only logical that Schultzenstein applied it to the blood at last, and designated as "*plasma*" the material of life present in the blood. In this way the formative and nutritive matter necessary to physiological life, as well as the plastic exudations occurring in diseased conditions, could be attributed to the same material—a highly satisfactory result in appearance, and one providing a most convenient basis for interpretations. The exponents of this notion had no scruples in going one step further and in providing this material of life with a technical name. They called it "*fibrin*." Evidently this did not quite correspond with Hunter's ideas, for we know of no such matter, either in the egg or in the plants or in the lower animals, as that to which he attributed simple life, but the necessities of pathology overcame all such scruples and the plastic exudations were received as undoubted evidence that fibrin possessed the power of becoming organised. They formed, in the crisis doctrine of the Vienna school, the bright spot of this newest kind of hæmato-pathology. Wherever fibrin failed, blastemata were brought to the fore. Ever since Schwann had given the name of cytoblastema to the organising material of the egg, the way had been open for assuming, in other places, the existence of material with this ambiguous name. But of course through these steps the one simple matter of life predicated by Hunter was replaced by many "*matters of life*," and thus the entire advantage gained by the exposition of a unitary theory of life was at once lost. Even when, finally, protoplasm was recognised as cell contents and thus the one requisite of Hunter—namely that the material of life must also be contained in the individual parts—appeared to be fulfilled, yet no single specific material was thereby arrived at. No one dreamed of regarding protoplasm as fibrin, and least of all did anyone consider it a simple chemical body.

By the conception of the blastema, however there had been reawakened a thought which had occupied the minds of men from the earliest times. If a plastic matter capable of being organised really existed in the body, then the organisation of the same must present the first reliable example of epigenesis. The problem of the "*generatio æquivoca*," which had been fought over for so long a time, now appeared to be solved. What Harvey had taught concerning the descent from the egg was rejected concerning the continuous descent from exudation. Several generations of young medical men have been educated in this belief. I myself remember my "*epigenetic*" youth with no little regret, and I have had hard work to force my way through to the recognition of the sober truth. Meanwhile, the attention of other bodies of inquirers

* Glisson, "*Anatomia Hepatis*," "*Ad lectorem*" 17

made the more exact method the ruling one, and at the same time to award to this country, which brought him forth, its important share in determining the new direction of our science. Nearly 100 years had passed since Vesalius and Paracelsus had begun their work when William Harvey published his "Exercitatio anatomica de motu cordis et sanguinis in animalibus." Here, for the first time, the anatomical examination of living parts was carried through, in an exemplary way, according to experimental methods. All the objections that anatomy concerned itself with dead parts only were thus at once set aside, living action became the object of immediate observation, and this was done on one of the most important organs, one absolutely necessary to life, the varying activity of which constantly calls for the attention of the practical physician. Not only so, however, but a new mode of observation—the experimental method—was thus brought into use for research, a method through which a new branch of medical science, physiology, has been laboriously built up. The influence of this one wonderful discovery of Harvey on the ideas of men of his time and of his successors was memorable. Among the men of his time the last support of Galenism disappeared with the proof of circulation, among his successors the comprehension of the causation of local processes dawned for the first time. Very ancient and highly difficult problems, such as inflammation, could now be attacked, a goodly piece of life also became intelligible since one of the vital organs themselves could now be subjected to experiment, and, to the astonishment of all, the action of this organ showed itself to be an absolutely mechanical one. The revulsion of thought was so complete that it has become since a difficulty hardly to be overcome to enter even in imagination into the ideas of the older physicians, to whom the circulation of the blood was unknown. Nevertheless, in spite of such striking results, the craving of man for more complete understanding remained unsatisfied. One saw the action of the living heart, but how did it live? What was this life the action of which one saw before one? In the heart itself the essence of life could not be recognised. Harvey turned his attention to another object, he tried to observe the very beginnings of life in the incubated egg of the fowl and in the embryos of mammalian animals. He thereby soon arrived at the question of the significance of the egg in general, and enunciated the celebrated dictum, "Omne vivum ex ovo." Owing to the more extensive researches of modern investigators, this dictum, as is well known, proved too narrow for the whole animal kingdom, and is no longer exact when applied to plant life. Its validity for the higher animals, on the other hand, cannot be questioned, and it has formed one of the firm standpoints on which researches on sexuality and on the propagation of life have been based, but Harvey, on account of the deficiency of his optical instruments, was unable to see that which he was labouring to discover—namely, the process of organisation as such, just as he had been unable in former times to see the continuity of the capillary flow. This imperfection lasted for a long time afterwards, and thus it happened that even Albrecht von Haller and John Hunter considered the formation of the area vasculosa in the incubated egg of the fowl as the commencement of organisation, and indeed, as the type of organisation itself. I will return to this point later, but for the present I should like first to draw your attention to a man whose importance for the further development of the doctrine of life has always appeared to me to have been uncommonly great and highly significant, but who, nevertheless, has sunk into unmerited oblivion, not only among posterity in general, but also, I think I may be allowed to say even in the memory of his countrymen. I mean Francis Glisson, who was a contemporary of Harvey, and whose works appeared almost simultaneously with those of his more celebrated colleague, but the brilliancy of Harvey's discoveries was so great that the light which shone from Glisson's work table almost disappeared. I rejoice that on so auspicious an occasion I may recall the memory of the modest investigator and may offer him the tribute of gratitude which science has to award him.

When, thirty five years ago, I published my little essay on Irritation and Irritability,¹ I did not know much more about Glisson, than every student of medicine learns—namely, that there is in the liver a "capsula communis Glissoni," and, what was even less known, that this anatomist had written a small work on "Rachitis," which, indeed, was the

first of its kind. In my own paper on this disease¹ I tried to demonstrate the circumspection and accuracy which are noticeable in this book, and which make it a typical model for all collective investigations, but even at that time I overlooked the fact that this was only the smallest merit of this wonderful man. It was only in the further course of my studies on the history of the doctrine of irritation and irritability that I made the discovery—an astonishing one to me—that the idea of irritability did not, as is generally thought, originate with Haller, but that the father of modern physiology and the Leyden school in which he had been brought up had borrowed this idea from Glisson. I then stumbled on a series of almost forgotten publications of this original scholar, especially his "Tractatus de natura substantiæ energetice seu de vita naturæ ejusque tribus primis facultatibus, perceptiva, appetitiva et motiva," which appeared in London in 1672, and in which the ideas were further worked out, the outlines of which had already been brought forward in his "Anatomia hepatis," published in 1654. In this work (p. 400) the newly coined word "irritabilitas" appears, so far as I can find out, for the first time in literature. It may be noticed, by the way, that the expression "irritatio" is much older. I find it already in Celsus, but with an exclusively pathological signification. It appears also occasionally in later writers, and to this day it has not, speaking accurately, lost this original signification. It is otherwise with Glisson, to him irritability is a physiological property and irritation merely a process of life dependent on the natural faculties of living matter. Thus he was led, through a process of "contemplation," to maintain the existence of the "blanchia," the "principium vitæ" or the "biusia," the "vita substantialis vel vite substantia." And in order to allow of no misunderstanding as to the source of his 'contemplation,' he adds distinctly that this is the "archæus" of Van Helmont—the "vis plastica" of plants and animals. In the further course of his philosophical discussions he nevertheless is led into the same by path which has misled, even in the most recent times, so many learned men and even excellent observers. This is the by path of unlimited generalisation. The human mind is only too prone to render intelligible what is unintelligible in particular phenomena by generalising them. Just as even in recent times an attempt has been made to render consciousness intelligible by representing it merely as a general property of matter, so Glisson thought he might attribute to the active principle ("principium energeticum"), which according to him is contained in all matter, the three faculties of living matter which he considered as fundamental—namely, the facultas perceptiva, appetitiva et motiva. All matter was sensitive, was thus stimulated to develop impulses, and moved itself as a consequence of these impulses. It is not necessary for the purpose of our present inquiry to carry these quotations further, since they are quite, in the Paracelsian sense, contemplative in their nature, and especially as, in their generalisation, they do not appear to be important for the history of advancing knowledge. That which is full of significance for us is concerned with actual life only, in the narrower sense of analytic science. It was not the "principium energeticum" set up by Glisson which stimulated his successors again to take up the thread of his observations, but rather this process of irritation described by him and the fundamental faculties of living matter on which it depended. In this way he has really led up to a more exact study of the actions of life and the properties of living matter. Unfortunately there intervened a mistaken conception, which led his followers again into a series of most serious errors. Glisson following on this point also the example of Van Helmont, was convinced that nerves contracted when irritated. He joined to this the idea that, through the contraction of the nerves, or even of the brain, the fluid contained in them was propelled towards the periphery. This notion, shared by Willis and many other physicians of that time, furnishes the reason why irritability was identified with contractility. Even the great master Hermann Boerhaave, and after him his pupil Gaubius, the first special writer on general pathology, considered sensation and motion as common properties of all events, all the solid parts of the body. The former thought it proved that hardly a single particle of the body existed which was not sensitive and did not move, and thus it becomes comprehensible how Haller himself carried this idea that irritability had the same significance as contractility

the tissues, but it soon became apparent that even the tissues are not simple substances. Since the third decade of this century the microscope has disclosed the existence of cells, first in plants and very soon afterwards in animals. Only living beings contain cells, and vegetable and animal cells show so much similarity of structure that one can demonstrate in them the actual product of organisation. This conviction has become general since through our embryologists, especially through Schwann, proof has been afforded that the construction of embryonic tissues was derived from cells also in the highest animals and in man himself. In the fourth decade of this century the science of pathological anatomy had already begun to be directed towards cells. These researches very soon struck on great difficulties. Many tissues, even in their developed state, appeared to contain neither cells nor their equivalents, nevertheless, I have been able to demonstrate their existence in those tissues in which their presence appeared to be most doubtful—viz., in bone and connective tissue. At the present time we are so far advanced as to be able to say that every living tissue contains cellular elements. We go a step further even, for we require that no tissue alone should be called living in which the constant occurrence of cells cannot be shown. A still greater difficulty then appeared—namely, to discover in what way new cells originated. The answer to this question had been very heavily prejudiced by the so-called cell theory of Schwann. Inasmuch as this very trustworthy investigator asserted that new cells originated from unformed matter, from ‘cytoblastema,’ there was opened up a wide road to the old doctrine of the ‘generatio æquivoca,’ which afforded all partisans of plastic materials an easy way of reviving their dogma. The discovery of cells of connective and allied tissues gave me the first possibility of finding a cellular matrix for many new growths. One observation followed another, and I was soon in a position to give utterance to the dictum, ‘Omnis cellula a cellula.’ And so at last the great gap was closed which Harvey’s ovistic theory had left in the history of new growth, or, to speak more generally, in the history of animal organisation. The begetting of a new cell from a previous cell supplements the reproduction of one individual from another, of the child from the mother. The law of the continuity of animal development is therefore identical with the law of heredity and this I now was able to apply to the whole field of pathological new formation. I blocked for ever the last loophole of the opponents, the doctrine of the specific cells of pathology, by showing that even diseased life produced no cells for which types and ancestors were not forthcoming in normal life.

These are the fundamental principles of cellular pathology. In proportion as they have become more certain, and lastly of more general value, they have also secured for themselves great importance in physiology. The cell is not only the seat and vehicle of disease, but also the seat and carrier of individual life, in it resides the ‘vita propria.’ It possesses the property of irritability, and the changes in its substance, provided these do not destroy life, produce local disease. Disease presupposes life, should the cell die, its disease also comes to an end. Certainly, as a consequence, the neighbouring and even far distant cells may become diseased, but as regards the cell itself the susceptibility to disease is extinguished with life.

Since the cellular constitution of plants and animals has been proved, and since cells have become recognised as the essentially living elements, the new science of biology has sprung up. It has not brought us the solution of the ultimate riddle of life, but it has provided concrete, material, anatomical objects for investigation, the properties the actions and the passions of which we can analyse. It has put an end to the wild confusion of fantastic and arbitrary notions such as I have just mentioned, it has placed in a strong light the immeasurable importance of anatomy, even in the most delicate conditions of the body, and lastly, it has made us aware of the close similarity of life in the highest and lowest organisms and has thus afforded us invaluable means for comparative investigation. Pathology has also its place, and one certainly not without honour in this science of biology, for to pathology we are indebted for the knowledge that the opposition between healthy and diseased life is not to be sought in a fundamental difference of the two lives not in an alteration of the essence, but only in an alteration of the conditions. Pathology has been released from the anomalous and isolated position which it had occupied for thousands of years. By applying its revelations not only to the diseases of man, but also to those of animals even the smallest and lowest, and to those of plants,

it in the best manner helps to strengthen biological knowledge and to narrow still more that region of the unknown which still surrounds the intimate structure of living matter. It is no longer merely applied physiology, it has become physiology itself. Nothing has more contributed thereto than the constant scientific union which has endured for more than 300 years between English and German investigators and to which we to-day add yet another link. May this union never be broken.

ABSTRACT OF

The Goulstonian Lectures

ON THE

CHEMICAL PHYSIOLOGY OF THE ANIMAL CELL

Delivered at the Royal College of Physicians on Thursday, March 5th,

By W. D. HALLIBURTON, M.D.,
F.R.C.P. LOND., F.R.S.,

PROFESSOR OF PHYSIOLOGY, KING'S COLLEGE, LONDON.

LECTURE II.

THE CHEMICAL CONSTITUENTS OF THE NUCLEUS, THE PROTEIDS OF CELL-PROTOPLASM.

[DR. HALLIBURTON resumed his discourse by considering the chemical constitution of the nucleus. He mentioned the fact that Dr. Lauder Brunton had been the first to investigate this subject, and referred to the labours of Miescher, Hoppe-Seyler, Kossel, Loew, Plösz, Von Jaksch, Geoghegan and Lubavin. The researches of these investigators together with the results recently obtained by Liebermann and Malfatti, rendered, he stated, a scientific classification of nucleins possible. He then continued.]

From the facts mentioned I should recommend the following slight modification of Hoppe-Seyler's classification of the nucleins. 1. Nuclein which contains no proteid, this is synonymous with nucleic acid. It occurs in nature in the heads of spermatozoa. Nucleic acid contains no sulphur. 2. Nucleins rich in nucleic acid and in their reactions very similar to the latter. These may be artificially prepared and occur in nature in the chromatic fibres of the nucleus. 3. Nucleins which are poorer in nucleic acid. They form numerous links in a chain and pass insensibly into those of the next group. They occur in nature in the nucleoli (pyrenin) and constitute the chief bulk of the substance called plastin. They may also be artificially prepared. 4. Nucleins which contain very little nucleic acid. They are chiefly proteid in nature and pass gradually towards proteids which contain no phosphorus whatever. They occur in the nucleus, it is difficult to be positive whether the nuclear matrix is chiefly composed of these or of phosphorus-free proteids, probably both are present. They occur in milk (caseinogen) in egg yolk (vitellin, ichthulin &c.) in aleurone grains of plants (plant vitellin) and in cell protoplasm generally (cell nucleolalbumen). The great insolubility in alkalis which characterises the nucleins of the third group is not seen in those of the fourth.

Having thus given a summary of our knowledge of the chemical structure of the nucleus I will next pass to a question which perhaps some here are asking. Has all this any practical bearing on medicine? The investigations are no doubt interesting from the scientific standpoint, they add point to the very ancient saying that we are fearfully and wonderfully made but do they help us at all in the everyday work of a physician's life? Let me preface my reply to this criticism by stating that all this knowledge is recent, and that the full practical bearing of all scientific research cannot be ascertained until a considerable time, often a very considerable time, after the theoretical standpoint has been fully

I have given prominence to Malfatti's views because they form an attempt to give a successful summary of the whole subject. Kossel however (Verhandlungen der Physiologischen Gesellschaft, Berlin, Oct. 21st 1892) strongly contests Malfatti's hypothesis that artificial nucleic acid is identical with that occurring in nature.

had been directed to the tissues of the body. Among these, in view of their importance, the nervous tissues, and especially the mass of nervous tissues in the brain and spinal cord, rank highest. Hunter also had acknowledged the importance of the brain, and hence called it the "materia vitæ concentrata." It was easily seen that it contained no fibrin, but experimental research showed also that neither the brain nor the spinal cord was of the same nature throughout all its parts. The more accurate the experiments the smaller became the region which, in the strictest sense, is the vital part, until Flourens limited it to one single spot, the knot of life ("nœud vital"). Was the unity of life found in this way? By no means. The brain is no more and no less vital than the heart, for life is present in the egg long before the brain and heart are formed, and all plants, together with an immense number of animals, possess neither the one nor the other. In the highly compound organisation of man the brain and spinal cord have a certain determining action on other parts necessary to life. Their disturbance may immediately be followed by the disturbance of other vital organs, and sudden death may ensue. But the collective death of a compound animal no more implies the local death of all its special parts than the local death of some of the latter is incompatible with the collective life of the animal. As has been well said, at the death of a compound organism there is a "primum moriens," a part which first ceases to live, then follow, at long intervals sometimes, the other organs, one after the other, up to the "ultimum moriens." Hours and days may pass between the total death of the individual and the local death of the parts. The fewer nerves a part contains, the more slowly usually does it die, I therefore consider the process of dying in the compound organism as the best illustration of the individual life of the several constituent parts, which is in its turn the first axiom necessary for the study and for the understanding of life. A long time, however, elapsed before it was possible to return to this starting point and to obtain a considerable number of supporters for the doctrine of the "vita propria." The attention of many observers was drawn to a totally different side of the question. In the last decade of the past century, about the same time that John Hunter, starting from careful anatomical investigations and exact observations of surgical practice worked out his idea of the material of life, a new system of medicine was founded in Scotland, the so-called Brownian system, which was based on quite different premisses. Brown also was a vitalist, he, too, constructed, not merely a pathological and therapeutic system of vitalism, but a physiological one, though his doctrine was dynamic in its character. There is but little to be noticed therein of the material anatomical foundation of exact medicine. It is concerned principally with contemplations of the forces of the living organism. One can understand to some extent how this happened if one keeps in view the history of the development of this extraordinary personality. I cannot go into this here, but anyhow the remarkable fact remains that the two contemporaries, Brown and Hunter, worked near each other without its appearing from their writings that they were acquainted with one another. Brown struck out his own line and stuck to it, without troubling himself about the rest of the medical world. And yet even his first work, "Elementa Medicinæ," had the effect of an earthquake, the whole European continent was shaken by it, and even the physicians of the recently opened New World bent under the yoke of revolutionary ideas, and in a few years the aspect of the whole field of medicine was entirely changed. True, the triumph was but short, the Brownian system disappeared as it had come a meteor in the starry heaven of science. There would be no reason to go into it more fully had not the impulse which he had given instigated other men, and been permanently applied by them to the true service of science. This impulse was founded on the fact that irritability, or, as Brown called it, "incitability," was thus reinstated as the starting point of the theory, but, along with this, the stimuli which set living substances in action, the "potestates incitantes," were brought to the fore. In so far that stimuli produce a state of irritation ("incitatio"), or, as Brown called it later, excitement they came to be viewed not only as the cause of health and disease, but even of life itself, for excitement, so he said, is the true cause of life. But, as excitement stands in a certain relation to the strength of the stimulus, a state of good health was only possible with a normal degree of stimulus whilst in excess or a lack of stimulus brought diseased conditions in its wake. Of course excitement is dependent also on irritability, with a certain quantity of which in the form of energy, every living being is endowed at the beginning of its life.

The division of diseases, according to the amount of vital force visible in them, into sthenic and asthenic has never been abandoned since, though acknowledged perhaps in a less precise manner, it has sometimes been brought more prominently forward and sometimes been thrown into the background. In Germany, Schönlein was the one of all others who took this doctrine as the foundation of his opinion on special cases of disease and for his guide in treatment. But the application of the Brownian principles to physiology has been of far greater importance. If life itself were dependent on external stimuli the notion of the spontaneity of vital actions, a notion still in force, must lose all significance. Certain stimuli would in that case prove to be necessary conditions of vital activity, without which life could at best be carried on in a latent form only. Certainly, even for this latent life, the question remained open, How does it come to pass and in what does it practically consist? Brown avoided this ticklish question, not without great skill, by drawing the whole attention to active life and to the stimuli which call forth action. To speak openly, science has since then deflected little, or not at all, from this guiding notion. Even now we cannot say what latent life is. We simply know that through external stimuli it may be converted into active life, and hence irritability is considered by us as the surest sign of life, not, of course, of the general life of all matter in the sense of Glisson, but of the real and individual life of special living organisms. Brown remarked, with reason, that through irritability the living substance is differentiated from the same substance in its dead condition or from any other lifeless matter. Nevertheless, neither irritability nor incitability, neither irritation nor incitation, explains the essence of the living substance, and therefore neither explains the essence of life. In Germany the physiologists especially took up this question. Among the first was Alexander von Humboldt, who in his various writings, especially in his celebrated treatise on the irritated muscle and nerve fibre, entered into the question. In the end he held fast to the assumption of a vital force. The majority of pathologists and physicians followed in his footsteps and long and fierce controversies were necessary before, nearly half a century later, the belief in a vital force was destroyed. When Dubois Reymond had demonstrated the electrical current in muscle and nerve in all its characters and, at the end of his work, had also disclosed the inadmissibility of vital force, then the venerable Humboldt formally and expressly renounced the dream of his youth, with the masterly submission of the true naturalist to the recognised natural law. The hypothesis of a vital force of life had, however, in regard to Brown's theory neither a positive nor a negative value. Johannes Müller rescued for general physiology, in which it has ever since kept its place, that which was valuable in Brown's system, the doctrine of the integrating life stimuli. The occasional stimuli which produce disease have found their place in etiology, their significance has become more and more sharply defined the more accurately we have learnt to distinguish between the causes and the essences of disease—a distinction which became more difficult as the "causæ vivæ" of diseases became known in ever increasing numbers. And now a new task has arisen—namely, to draw into our sphere of observation the life of the causative agents themselves.

The way in which pathology has tried to approach the desired goal, to fathom the living substance in its diseased conditions, has led us a great step forward. Pathological anatomy especially has opened this road. The more numerous its observations and the more it penetrated into the details of the lesions the smaller became the field of so-called general diseases. The first steps of mediæval anatomists had the effect of drawing the attention to local diseases. In the first and longest period, which one may define as that of Regionalism, the pathological anatomists sought the cause of disease in one of the larger regions or cavities of the body—in the head, chest or abdomen. In the second period, ushered in by the immortal work of Morgagni, shortly before the time of which I last spoke—the time of Brown and Hunter—they endeavoured to find in a certain region the actual organ which might be considered as the seat of disease. On this foundation arose the Parisian school of Organicism which, until late in this century, held a dominant position in pathology. In this school already they recognised that not the organ, nor even a portion of it, could be the ultimate object of research. Xavier Bichat divided the organs into tissues, and showed that in the same organ sometimes one and sometimes another tissue might be the seat of disease. From that time forward the eye of the pathological anatomist was directed chiefly to the changes in

tained in, or rather obtainable from cell protoplasm. No mucin is generally extra-cellular though of course it originates intra-cellularly. Thus it is found in the matrix of connective tissues and in the various secretions which are poured out from the cells. Nucleo-albumens, however, are not confined to cells; they are found also in secretions, caseinogen, the chief protein in milk, is one, though it has not the viscosity characteristic of those in protoplasm. The so-called mucin of the bile is another, and more recently still it has been shown that the mucino-d substance in the mucus of the urine is not mucin at all, but another nucleo-albumen shed out from the cells of the urinary tract. Coming now to the two globulins I described as obtainable from lymph cells I labeled them cell globulin C and cell globulin B. Cell globulin C is characterized by coagulating at the remarkably low temperature of from 47° to 50° C and by a readiness of precipitation by comparatively small quantities of neutral salts like magnesium sulphate or sodium chloride. Cell globulin B coagulates at a higher temperature (from 60° to 70° C in different solvents) and requires complete saturation with magnesium sulphate in order to precipitate entirely. It also possesses fibrino-plastic properties, and I felt justified in concluding that cell globulin B was the product of the disintegration of the leucocytes which has long been known under the name "fibrin-ferment." I shall have to return to this point in connexion with the subject of blood coagulation. Cell globulin S did not show the viscosity which at that time I considered as characteristic of nucleo-albumens and so I did not subject it to analysis. This, however, has been done by Peseharing of Utrecht, who finds that it is a nucleo-albumen. Whether it is a portion of the same nucleo-albumen which one obtains by the sodium chloride method or whether it is still uncertain. I have since obtained abundant evidence that many nucleo-albumens exist the solutions of which are not viscous and further that a nucleo-albumen may be made viscous by treatment in one way and may by another method be obtained without this physical characteristic. This other method is that originally employed by the late Dr. Wooldridge in the preparation of what he termed tissue fibrinogens. These substances have in recent years been the subject of numerous papers by Wright and Peseharing and both thoroughly confirm my hypothesis that the chief constituent of "tissue fibrinogen" is nucleo-albumen. By either of these methods an abundant supply of the nucleo-albumen may be obtained in fact, so great is the yield that there can be no doubt that the amount of nucleo-albumen is far in excess of the amount of globulin. I am not prepared to state positively that these substances may not in part originate from the nuclei. The nuclei when examined microscopically in the residue appear practically unaltered, they are, however, a little swollen after treatment by sodium chloride. The yield of material appears too large to come altogether from the nuclei, and moreover it is a matter of difficulty to obtain nucleo-albumens from every organ rich in nuclei. This is notably the case with the liver. One can therefore hardly resist the conclusion that the nucleo-albumen originates chiefly from the cell protoplasm.

So far I have been speaking of cells in general, but with especial reference to lymph cells, I may now pass on to the various organs and tissues to which I have now extended similar observations. The full investigation of all of these is at present incomplete, and it has been the nucleo-albumens which have generally attracted the most attention.

The Liver.—Here as one would anticipate from histological resemblances, the chemical resemblances are also very great. There is the same globulin coagulating at from 47° to 50° and an abundance of nucleo-albumen obtainable either by the sodium chloride or the acetic acid method. Indeed so abundant is the supply of the latter that for experiments on intra-vascular clotting I am in the habit of using this organ for the preparation of the material in question.

The Kidney.—Here again, the nucleo-albumen can be prepared by either method. It contains 0.37 per cent. of phosphorus. Here, also, the globulin which coagulates at from 47° to 50° C is present. Indeed, it seems that this globulin is as characteristic of cells as the nucleo-albumen itself.

The Lungs.—My results with this organ may be summed up as follows. Four proteins can be extracted from liver cells by dilute saline solutions, in all of these an albumen is present

in the mere traces, two of them are globulins differing in their heat coagulation temperatures (hepato-globulin A coagulating at from 45° to 50° C, hepato-globulin B coagulating at from 65° to 70° C) and in the readiness with which they are precipitated by neutral salts. The remaining protein is a nucleo-albumen, but the yield of nucleo-albumen is small. It may be that the liver cells contain a good deal, but the methods adopted for its extraction only get out a small quantity—indeed, the sodium chloride method of preparation is quite inefficient, one, therefore, has to fall back on Wooldridge's acetic acid method. The liver nucleo-albumen resembles that of the kidney, thymus, testis and lymph gland in producing intra-vascular coagulation, but differs from these in its heat coagulation temperature in not being rendered viscous by admixture with salt and in its high percentage of phosphorus (1.45 per cent.).

The Nervous System.—The fact is very often lost sight of how rich nervous tissues are in protein matter. Fifty per cent. of the solids in grey matter and about 50 per cent. of those in white matter are protein in nature. This was originally pointed out by Petruszky, and I have made a large number of quantitative experiments that have verified the truth of this statement. Grey matter also contains considerably more water than white matter and if one analyses any nerve tract containing both grey and white matter the amount of grey matter, of water and of protein will vary directly the one with the others. The nature of this protein next attracted my attention. If one extracts a blood-free brain or spinal cord with saline solution one obtains a solution of three proteins which are all precipitable by saturation with magnesium sulphate, and so at first I erroneously concluded they were all globulins. This error was confirmed by the fact that the sodium chloride method of extracting nucleo-albumens gave a negative result. Finding, however, that by Wooldridge's method I was able to prepare a very good supply of nucleo-albumen, especially from grey matter, which was extraordinarily active in producing intra-vascular clotting I returned once more to my three supposed globulins. The first of these coagulated at from 47° to 50° C and was precipitable by comparatively small quantities of salts. On gastric digestion it left no residue of nucleus. It therefore is a true globulin analogous to others I have already mentioned. The next protein coagulated at from 55° to 60° C. This, however, was only obtainable from grey matter, white matter yielded the mere traces. I left a considerable residue of nucleus after gastric digestion, it therefore is the nucleo-albumen, it contains 0.5 per cent. of phosphorus, the same percentage as was found in the nucleo-albumen prepared from grey matter by Wooldridge's method. The third protein which coagulated at about 70° C, was again a true globulin.

The Spleen.—This organ has been investigated by Dr. F. Gourel in my laboratory, and although his results are not yet complete he has kindly allowed me to state that he finds the proteins closely analogous to those in other cellular structures. The nucleo-albumen is capable of preparation by either method. There is also the protein present which coagulates at from 47° to 50° C. In connexion with the spleen there are other points of interest to be noted. My predecessor in his lectureship, my friend Dr. Sidney Martin, stated that in certain infective diseases the spleen is a centre for the accumulation of the protein poisons the albumoses that cause the characteristic symptoms of cachexia, tetanus and so forth. Almost simultaneously with Dr. Martin's lectures von Jaksch* stated that the normal spleen is rich in "peptones" (the word peptone as used includes proper one (proteoses or albumoses). The proteoses Dr. Martin obtained from spleens in cases of disease had certain specific actions, nevertheless appeared important to investigate the physiological action of those obtainable from normal spleens. This task has been considerably lightened by finding that the fresh spleen like other organs and tissues contains no peptones or proteoses at all. We have used the same methods as those adopted by von Jaksch, except that we have taken care that the spleens were perfectly fresh and from healthy animals. Dr. Martin has been good enough to supply as well as some he has had the opportunity of obtaining. If spleens are obtained from the bodies a small quantity of protease is usually obtainable but this is doubtless as I have already stated, formed post-mortem from the splenic cells and leucocytes.

The Thymus Gland.—This organ has also been investigated by Dr. Gourel and his general results are practically identical

* Wooldridge chiefly used the substance prepared from the testis by the acetic acid method. The testis does yield an active product by the sodium chloride method also.

established. I need not weary you with instances of how scientific work which at the first blush appeared of no practical benefit to mankind has in the end proved to be full of the highest usefulness. But in the present case there are indications already that the application of our chemical knowledge of the nucleus will assist us in the elucidation of certain pathological problems, and the one to which I shall call your attention is that of the formation of uric acid. Amongst the products of decomposition of nuclein are certain nitrogenous bases, one pair is adenine and hypoxanthine, the other xanthine and guanine. Adenine has the formula $C_5H_5N_9$, on heating it with sulphuric acid, NH is replaced by O, and hypoxanthine is thus formed—

Both substances contain a radicle $C_5H_4N_4$, which Kossel terms "adenyl", adenine is its imide, hypoxanthine is its oxide. The following equation shows a similar relationship between guanine and xanthine—

Now on comparing the formulae of hypoxanthine and xanthine with that of uric acid we have $C_5H_4N_4O$ =hypoxanthine, $C_5H_4N_4O_2$ =xanthine, $C_5H_4N_4O_3$ =uric acid. In other words, here is a series of three substances, each differing from the preceding by an atom of oxygen. Leaving aside other ways in which uric acid may be and undoubtedly is formed in the organism, we have here a possible way in which, by a process of oxidation, uric acid is formed from xanthine and hypoxanthine, and thus ultimately from the nuclein of cells. This possibility has been put to the test by Horbaczewski, who has obtained very interesting positive results. This investigator is well known as one who attaches great importance to the spleen as the seat of formation of uric acid, and it is in connexion with this organ that he has performed the principal experiments in his recent researches also. He finds that by passing air through a mixture of fresh splenic pulp and defibrinated blood at from 37° to 40° C., considerable quantities of uric acid are formed, if, however, oxygen is excluded, no uric acid appears, but an equivalent portion of xanthine and hypoxanthine is formed instead. With the idea that the nuclein of the splenic cells might be the source of these products, he prepared some nuclein from spleen and obtained it in large quantities as an insoluble residue after the gastric digestion of splenic pulp. Next, in treating this as he had previously treated splenic pulp, he obtained from it either uric acid or its equivalent of xanthine and hypoxanthine according as oxygen was present or not. Passing to other organs he discovered that this was no essential property of splenic pulp or splenic nuclein, but that all organs rich in nucleated cells behaved in a precisely similar way. The next step in the investigation showed that uric acid was increased in the urine of animals after food, especially after food which, like meat, caused an increase of leucocytes in the blood. Subcutaneous injection of nuclein led to a great increase in the uric acid excreted. This occurred both in animals and in human beings, and, further, in certain cases of anaemia it was found that food caused no increase in the leucocytes. In these there was also no rise in the excretion of uric acid. The influence of drugs was also investigated. Quinine produces a fall in the number of leucocytes and a fall also in the elimination of uric acid. Atropine acts in the same way. Pilocarpine produces the opposite effects. Rather curious results were, however, obtained with antipyrin and antifebrin, they produce an increase in the number of leucocytes but a fall in the uric acid. This is explained by the hypothesis that although the leucocytes are more numerous they are not destroyed so rapidly. This explanation was controlled by microscopic examination which showed the leucocytes to be in an atrophic condition after quinine and atropine, whilst after pilocarpine they were active and undergoing karyokinetic changes. Lastly, the condition of things in various pathological conditions showed that wherever there is leucocytosis there is also an increase in the output of uric acid, and the theory that it originates from nuclein is considered to be borne out very fully. In leucocythæmia the rise in uric acid excretion is a very marked symptom, and I venture, amidst the various conflicting ideas now current as to the meaning of uric acid and the causes of variation in its amount in disease, to put forward these views of Horbaczewski as worthy the serious consideration of pathologists and physicians.

It is now, however, time to leave the nucleus and to pass to the consideration of the proteids of cell protoplasm. First with regard to its reaction. This is in the fresh state always alkaline, but after removal from the body it invariably becomes acid after a time. This acidity is in part probably chiefly due to the development of sarcos-lactic acid. It may also be partly owing to the formation of acid phosphates from the neutral phosphates of the tissue. In one tissue—namely, muscle—this change in the acid direction has long been known and probably assists in the disappearance of rigor mortis. Muscle, like many other tissues, contains a small quantity of pepsin which has been absorbed from the alimentary canal. This was pointed out by Brucke many years ago. Under ordinary circumstances there is no self-digestion of these tissues, any more than there is any self-digestion of the stomach walls. But after death, and after the development of acid, particularly if the body is kept in a warm temperature, this self-digestion does occur and small quantities of peptones and proteoses will be found. I feel inclined to believe that this self-digestion is in great measure the reason why the hardness of the muscles known as rigor mortis becomes less and less as time goes on. No doubt in many cases this is assisted by putrefactive changes, but these do not appear to be constantly present. The peptones that have been stated to occur in various tissues are thus seen to be formed post mortem. Healthy fresh tissues do not contain peptone, nor do they contain those intermediate products in the formation of peptones which are called albumoses or better, proteoses. The fresh tissues do not contain albumen either, or only in the merest traces. I have used the word albumen not in the wide sense in which it is sometimes loosely employed as synonymous with protoid, but in the stricter sense of a protoid which is soluble in water and in sodium chloride solutions of all strengths, and further one which is coagulated by heating it. I began my investigation of this subject now several years ago and selected as the starting point lymph cells obtained from lymphatic glands as a convenient instance of typical animal cells and then found three proteids, two of them globulins and the third a nucleo-albumen. We will take the nucleo-albumen first. It is a protoid which in some of its physical properties is very like mucin, it was called hyaline substance by Roida and was described also by Miescher in pus cells. It may be prepared as follows. The tissue, freed from blood and lymph, is cut into small pieces and ground up in a mortar with about an equal amount of powdered salt (I usually employ sodium chloride, but magnesium sulphate does as well). A small quantity of water is added and the whole thoroughly mixed, the resulting mass is exceedingly viscid. This mucinoid mixture is then poured into a tall vessel containing water, the globulin is precipitated in a finely flocculent condition and falls to the bottom of the vessel together with the residue of the pieces of tissue. The nucleo-albumen is precipitated throughout the water in the form of cohesive strings, which very rapidly contract and finally collect in sticky lumps which float upon the surface of the water. These are collected and thoroughly washed with large quantities of water. The substance can be purified by a repetition of the treatment with sodium chloride. Finally, it can be dissolved in a weak solution (1 to 5 per cent.) of sodium carbonate. If one has performed the manipulations rapidly the solution is complete, if one delays and leaves the protoid matter too long in contact with the sodium chloride, its solubility in dilute alkaline solutions is considerably diminished. This method of preparing nucleo-albumen I shall have frequently to allude to in the remaining portions of these lectures, and I may speak of it as the "sodium chloride method." When I first came across this remarkable substance the idea that it was mucin was regarded as not an improbable one. Mucin is a substance which is continually being formed within many cells from their protoplasm as a result of their metabolic activity. The substance is, moreover, like mucin, soluble in alkalis and precipitable from its alkaline solutions by acetic acid. Moreover, it is viscid like mucin. But, putting this to the test of experiment, one soon discovered that all is not mucin which is sticky. Mucin is a glucoside—a compound of a protoid with a carbohydrate called animal gum—and by boiling with sulphuric acid it yields a reducing sugar. This material does not do so. On gastric digestion an insoluble residue of nuclein is left behind which is identified by its reactions and especially by the high percentage of phosphorus it contains. This nucleo-albumen is not characteristic of lymph cells, but either it or a member of the same group is found wherever there are cells. It appears to be the most constant of the proteids con-

fever in which there is only a little sore throat, perhaps only a faint rash, perhaps only slight desquamation without any rash having been observed. It is open to doubt whether the limits of possibility in the way of modification have even then been reached. Since there are gradations of severity of attack, down to those which are recognised with difficulty and by indirect evidence, it becomes a question whether there may not be a continuance of the gradation below the clinical horizon altogether. A hint to this effect is given by the excessive fatality of bronchitis and pneumonia at times when measles, whooping cough or influenza have been epidemic, of kidney diseases after scarlet fever epidemics, and the like. Many of the deaths so recorded doubtless follow upon well marked attacks of the antecedent zymotic, but this can scarcely be the case with all. The "shadow wave" usually accompanies or follows closely upon the zymotic wave. The death certificates in the majority of instances would not omit a reference to a known attack—say of measles—occurring within a few weeks of the fatal issue of a case of bronchitis, especially as by hypothesis the complication which causes death is the direct outcome of the zymotic disease. If both measles and bronchitis were mentioned on the certificate the death would be credited to the former and not to the latter, preference being given to the zymotic in accordance with general rule. It would seem, therefore, that if the increased mortality attributed to respiratory disease, which accompanies and follows epidemics of measles be really due to measles, the antecedent attacks of measles must not only escape mention in the certificate, but must, as a rule, have escaped notice altogether. The number of deaths attributed to kidney diseases at ages under ten years rises and falls with the scarlet fever death rate year by year and must, therefore, follow closely upon the antecedent scarlet fever, since the latter reaches its seasonal maximum in late autumn. Had the secondary curve attained its maximum in the following year it might have been supposed that the absence of mention of scarlet fever in the certificates was due to lapse of time.

During an epidemic of influenza the general death rate increases greatly, and particularly the mortality from phthisis, respiratory diseases and heart disease. Indeed, the Registrar-General infers that in January, 1890, the deaths directly attributed to influenza were only about a sixth of those actually caused by it. Unperceived attacks may also contribute to the explanation of the immunity from certain diseases conferred by residence in localities where they are endemic. Acclimatisation seems to be almost limited to diseases of the mobile class, which are only slightly protective. Long and continuous residence in a malarious region confers some immunity, which is lessened or lost in case of temporary removal to a non malarious country. This seems to imply a necessity for constant renewal, and to negative the alternative view that the immunity is simply the expression of a natural insusceptibility, demonstrated rather than caused by the previous exposure to malaria. Something of the nature of a constantly repeated slight infection suggests itself as a possible explanation of the temporary immunity, and also of the fact that changes in the internal organs may be found in persons who have escaped any known attack. It has been observed, too, that in districts where enteric fever is endemic its incidence is disproportionately great upon newcomers older residents escaping more easily. Young troops newly quartered in certain Indian stations have been found to suffer much more heavily from enteric fever than their seniors, whilst natives are affected least of all. As regards influenza there is room for suspicion of acclimatisation in another sense, although the uncertainty as to the identity of the affections so named precludes any very definite conclusions. The well known instances of St. Kilda and Wharekauae¹ lend themselves to such an explanation. These are small insular communities far removed from ordinary traffic and it is recorded that the arrival of strangers is almost always followed by the rapid diffusion of a catarrhal illness amongst the inhabitants, no matter whether the newcomers are or are not suffering from any catarrhal or other symptoms. Assuming the malady to be the same time after time, it would seem not to be lastingly protective, since the outbreak is repeated upon each new arrival, nor is it capable of establishing itself upon a permanent footing. It seems clear, too, that the islanders are more susceptible than the visitors. If it be granted that amongst the many kinds of cold, catarrh and febricula which are prevalent in all large communities

there are some which are infectious and slightly protective, and readily capable, moreover, of attenuation and intensification, the exaggerated susceptibility of secluded islanders is not difficult to explain. The strangers are "acclimatised" to the disease they bring, but the islanders are not.

Amongst diseases of fixed type the interval between epidemics may be bridged over by sporadic cases or the disease may disappear altogether and await reintroduction. There are other possibilities as regards the opposite group. Some of them may lurk in outside media, for periods to which it is difficult to assign any limit, or the continuity may be eked out by attacks in lower animals. Farther than this, the disease may assume and retain a mild type, so mild, it may be, as to escape recognition. The modified attacks, which are readily identified when they occur in association with severer forms during an epidemic are less so when they occur alone. Diphtheria, erysipelas, influenza and pneumonia have already been referred to in this connexion. Murchison says of typhus fever "It is probable that many cases of so called febricula, where the fever only lasts for two or three days and is not attended by rash, occasionally result from a small dose of the typhus poison, at all events, cases answering to this description sometimes occur in the same family, and at the same time, as true typhus." Occasionally in crowded manufacturing towns and villages we meet with typhus fever outbreaks which at the present day we cannot suppose to have arisen *de novo*, but which seem to have had their beginnings in cases of illness which, apart from subsequent history of typhus fever, would have received no name more definite than febricula or simple continued fever. Mr Spear directed attention to the occurrence of a mild form of typhus fever amongst children in connexion with such outbreaks, and Dr Theodore Thomson has suggested as probable "the more or less universal existence of a specific organism which under ordinary conditions does not develop sufficiently to display its potential infectivity, but which under special conditions may so develop."² Amongst diseases of more constant type the modification never goes so far as to cause doubt of their identity, except in individual attacks where the resistance is high.

The varying quality of epidemic diseases has to be taken into account in all epidemiological inquiries. The relation of scarlet fever to rainfall may serve as an example. Dr Longstaff has shown that, broadly speaking, scarlet fever is most fatal in years when the rainfall is low, and least fatal in years of high rainfall. The recognition of varying phases of virulence makes the relation still more close, for it enables us to account for the occasional occurrence of high mortality in wet years and low mortality in dry years. Other things being equal, the greater prevalence in dry years will bring about higher mortality, but, as the percentage of fatal attacks varies from 1 to 15 prevalence is not the only important consideration. There is, however, some reason to suspect that the cycle of severity as well as the varying prevalence may have a direct or indirect relation to run, but, at best, annual totals of rainfall are very crude data. The necessity for much more measured detail is shown by the fact that the mean annual curve of rainfall attains its maximum (not minimum) at the same time as the scarlet fever curve.

Attempts are constantly made to estimate the effects of preventive measures by comparison of periods before and after their adoption. For want of a better basis, death rates are often used as a measure of prevalence, on the tacit assumption that the case mortality and type remain constant—an assumption which is far from being sound, and in taking the mean of a number of years as representing the average mortality from a given disease some regard must be paid to its cycles of increasing and lessening energy. It would be unsafe to draw conclusions as to the effect of preventive measures upon scarlet fever for example, from the comparison of periods shorter than fifteen years, seeing that until lately the tendency was to a cycle five or six years in duration, and as each successive wave after 1870 was lower than its predecessor and the rhythm has now ceased to be evident other elements of uncertainty come in. For the real question at issue is Has the course of the disease been different to that which it would have followed had the supposed preventive measures not been adopted? It is scarcely possible to answer this question by crude statistics of deaths, for quality as well as quantity have changed and social as well as climatic influences are far from constant.

² Public Health, May, 1890.

with those just mentioned. There is, however, this point about the thyroid: it is possible that the colloid matter in the vesicles is a nucleo-albumen, or the source of the very active nucleo-albumen which is obtainable from this organ. Here micro chemistry in the shape of the phosphorus reaction introduced by Lilienfeld and Monti has come to the rescue. We tested the method in some preliminary experiments with sections of the thymus. We found the cells, and especially their nuclei, stained a brown colour, the corpuscles of Hassall were more deeply pigmented than the rest, the circumferential regions of the alveoli were more deeply stained than their interiors. The muscular coats of the small vessels also stood out very prominently. Having in this way convinced our selves of the applicability of the new method, we proceeded to a similar investigation of the thyroid. We found that the colloid matter stains as deeply as the cells and that it is probably a nucleo-albumen. The colouration is not due to lecithin, as after the sections have been treated with alcohol the colloid material still gives the reaction. This view is confirmed by the fact that we have been unable to get a reducing sugar by treating the thyroid with sulphuric acid. The thyroid is an organ which is just now attracting much attention, and we can only hope that these investigations may throw some light on the question to which of its constituents is the wonderful curative effect of thyroid juice in myxœdema due?

Muscle—This tissue has been studied by Mr Whitfield, medical registrar to King's College Hospital. He has especially investigated the question whether this tissue contains nucleo-albumen, his work is not yet complete, but I may mention that he has hitherto obtained only negative results.

The practical importance of investigations on cell protoplasm seems to me to lie chiefly in the fact that it is impossible properly to understand the phenomena of phagocytosis and chemotaxis until we know the chemical composition of cells. Another path into which these investigations lead is the question of the protective proteids and immunity generally. The alexines or protective proteids are related to, if not identical with, cell globulin β (now shown to be a nucleo-albumen), and this line of research has been followed, with valuable results, by Hankin, Bachner and others. But they have led me into still another channel—namely, into a renewed investigation of the question of blood coagulation, and it is this subject that I propose to discuss in my third lecture.

The Milroy Lectures

ON

CHANGES OF TYPE IN EPIDEMIC DISEASES.

LECTURE IV

Delivered at the Examination Hall, Victoria Embankment, on March 2nd, 1893

By B. A. WHITELEGGE, M.D., B.Sc. LOND

Accumulation of Susceptible Persons—Varying Susceptibility of Individuals and of Classes—Limits of Attenuation—Unperceived Attacks—Acclimatisation.—Inter epidemic Conditions—Difficulty of Measuring Influence of External Conditions—Summary

MR. PRESIDENT AND GENTLEMEN,—Amongst the influences which promote or check the growth of an epidemic are those which bring about accumulation or lessening of the susceptible units in the population. This accumulation varies in meaning. As regards malarial fevers, it simply implies that a number of persons susceptible to malaria of a given degree of intensity are placed within range of the miasma. Proximity of person to person has no apparent importance in itself. In the next group, including diphtheria and erysipelas, concentration of susceptible persons becomes significant, as well as their individual exposure to infection. Not only may they become infected one from another as well as from non living media in which the contagium is able to exist, but if their proximity be sufficiently close (in school or in hospital, for example) it seems that the poison may become intensified, increasing in virulence as well as in quantity. In diseases of more stable type, such as small pox and measles, the effect

of accumulation is again simple. It is a matter of greater or less facility of transmitting infection from A to B. But at every point other controlling conditions are in operation. The sufficiency of accumulation is dependent upon the constantly changing seasonal or "accidental" conditions of weather, upon school influences and other social factors, and upon intentional or unintentional precautions in the way of isolation of the sick. Moreover, the power of the contagium to overcome obstructions to its diffusion may be variable in its different phases of intensity. And, lastly, susceptibility is a relative term, not constant in itself as regards either individuals or populations and dependent further upon the potency of the contagium. Susceptibility to a severe epidemic type does not necessarily imply any susceptibility to a milder phase of the same disease, nor is it constant in a given person under different conditions or at different ages. In small pox, for instance, there are all degrees of susceptibility, from complete absence of natural or acquired immunity down to a vanishing point amongst those who have recently been vaccinated or who have recently recovered from small pox. The different classes are exposed to the same infection, and it is found that, as the protection—measured in terms of more or less vaccination, more or less recent—diminishes so does the liability to attack increase, and with the liability to attack the average severity of attack. Notwithstanding the assumed constancy of type, we find mild and fatal attacks side by side and infected one from the other. The mild case is mild not because of any attenuation of the virus, but because the resistance is great, and, so far as small pox is concerned, it seems to make little difference in the character of attack whether the infection be derived from a slight or severe previous case. The epidemic type is masked, but not altered, by the resistance of the individual. This can scarcely be affirmed as regards diseases of mobile type, such as diphtheria, and it is doubtful whether it is so in scarlet fever.

It is not always a simple matter to determine the relative susceptibility of different classes of persons—for example, the two sexes. Mortality returns show that whilst most zymotic diseases kill more males than females, the balance is reversed in diphtheria and whooping cough. The conclusions naturally suggested by these data are somewhat modified by the observation that the attack rate by no means necessarily corresponds to the death rate if calculated for the two sexes separately.

Metropolitan Asylums Board Hospitals, 1871-91

Malady	Sex	Cases.	Deaths.	Case mortality
Scarlet fever	Male	10,881	2,061	19.3
	Female	22,224	1,893	8.5
Enteric fever	Male	4,041	670	16.7
	Female	3,674	662	17.3
Typhus fever	Male	961	216	22.4
	Female	1,176	217	18.5
Diphtheria (1888 to 1891)	Male	1,367	478	35.2
	Female	1,715	555	32.4

Scarlet fever, diphtheria and typhus fever attack more females than males, but the case mortality is higher amongst the latter, and, conversely, enteric fever shows a heavier incidence upon males, coupled with a lower case mortality. In each instance the greater incidence is associated with the lesser fatality. This raises a suspicion of unequal facilities for infection, of "super added waves," and more detailed information is needed before the true relation of sex to these diseases can be finally established. To take another example, the greatest incidence of attacks of scarlet fever is in the fifth year of life, but the greatest case mortality is in the second year. Possibly the difference may prove to be due to some unequal exposure to infection, which up to five years of age brings about a greater and greater liability to attack, notwithstanding a lessening susceptibility. After the fifth year, it may be supposed, the increasing exposure is no longer able to counteract the still increasing immunity, and the incidence of attack grows less year by year.

Whether from high resistance, as in small pox, or from low infectiveness, as in diseases of inconstant type, attacks occur which are so slight as to be scarcely recognisable. Such for example, are the slight forms of small pox, with perhaps only one or two doubtful papules, the slight forms of diphtheria which are indistinguishable from simple sore-throat, and which are only diagnosed on giving rise to diphtheria in others or on being followed by paralytic sequelæ. Such, too, are the slight cases of typhus fever which pass for "febricula" or "simple continued fever," and the slight cases of scarlet

long in developing. There was a history of a fall from a perambulator when some months old, but I do not think much importance is to be attached to this. Her rate of growth had been about one inch annually. As regards the history of former treatment, the parents had seen several consultants. No medicines, of course, had caused any improvement, but general massage seemed to have brought about some amelioration. Up till April, 1892, any treatment I employed was on account of some special symptom—e.g., eczema, which was very troublesome, or constipation or other complication.

Treatment—In April, 1892, I got the parents to consent to try the effect of the hypodermic injection of thyroid extract. I began with ten minims twice a week, but after about twelve injections the mother found that the child was restless, irritable and sleepless, and apparently worse after the injections. Accordingly I reduced the injection to ten minims weekly, there after every second week, and on three occasions left four weeks between the injections. This brings us down to October, when I began the feeding with the raw gland, giving half a lobe per week at first, then, after two weeks one lobe per week, when I tried two lobes one week, and by this time found the temperature normal, but the child was evidently "out of sorts," so the amount was reduced to one

appearance after nine months' treatment, six months by hypodermic injection and three months by feeding with raw gland. During the nine months the child has grown fully four inches, the supra-clavicular pads have quite disappeared, the appetite has improved amazingly, her dietary being a much larger one now, the constipation is gone, the umbilicus no longer protrudes, and there is no tendency to eczema. The temperature remains at about 97° F. The improvement is such that a friend and regular visitor at the house, who had been absent for some weeks, on seeing the child, did not recognise her, and thinking she was a stranger asked whose child she was. One point I may mention—namely, that prior to the thyroid treatment there frequently appeared a dark, almost black, part on the scalp, which after increasing in depth of colour came away in scales. I judged it to be a coloured sebaceous secretion.

I have also had two cases of myxœdema in adults which I treated with extract and feeding, with markedly beneficial results, but many such cases have already been reported.

London-street, Edinburgh

THE CHOLERA EPIDEMIC IN RUSSIA

By FRANK CLEWOW, M D EDIN & C

NO I.

IN CENTRAL ASIA AND SIBERIA.

(Continued from p 516)

IN marked contrast with the comparative intensity of the epidemic in Ural'sk was its mildness in the province of Turgai, lying immediately adjacent on the east. The first cases were reported from there on July 24th, and the whole province escaped with the small loss of 296 cases with 167 deaths. The inhabitants of both these provinces are mostly Kirghiz and Kalmuck Tartars, living a more or less nomadic life. Their water supply is derived from rivers and wells, the river water is said to be of satisfactory quality, but the well water is less so, whilst in the dry season the tribes drink extremely polluted water from lakes, not, however, without a rough process of filtration or, rather, straining. As early as July 14th cases were reported from Omsk and the large district of which it is the principal town. This district contains the three provinces of Akmolinsk, Semipalatinsk and Semiretchinsk, and is known officially as the General Governorship of the Steppes. The numbers of cases and deaths were at no time very high from any of these provinces, of which Akmolinsk was the greatest sufferer. The totals for the whole of this immense district were only 2133 cases with 1124 deaths, representing a case-rate of 118 and a death rate of 62 per 100,000. These figures sink into insignificance when compared with those of the neighbouring province on the north. In this province, the government of Tobolsk, the epidemic raged with great violence. The first cases occurred on July 17th, and the total number reported was 26,301, of which 12,729 proved fatal, the proportion of cases and deaths to the population being expressed by the figures 1865 and 903 respectively. In the middle of July cases of cholera were reported amongst exile prisoners in the town of Tomsk, and from this distant government there were, in all 4697 cases and 2272 deaths. Finally, the disease was reported from Irkutsk on Aug 2nd and from Yeniseisk on the 4th but in neither of these northerly governments did it attain any hold.

The following table gives the numbers of cases and deaths, the proportion of both to the population, and the ratio of deaths to cases in each division of Asiatic Russia beyond the Caspian Sea during the whole course of the epidemic. For these figures as well as for much valuable material and information, I am indebted to Dr Ragozin, the Director of the Medical Department of the Ministry of the Interior, whilst for kindly revising and verifying all the statistics given in this paper my thanks are due to Dr Grebentschikoff, the head of the statistical division of the same Department.

lobe a week and was continued at this till recently, when one lobe and a half were given. It was administered in cool beef tea.

The result of the thyroid treatment was continuous improvement. After the first few injections the appearance of the child had completely changed, there was a marked diminution in the size of the abdomen, so that a bodice which fitted before the commencement of this treatment now overlapped by four or five inches. The thick lips and alae nasi were now of normal size, the skin was pliant and soft, the temperature to touch improved, and the hair apparently more healthy, though still sparse. As week by week passed some mark of improvement was always seen. In October the child began to walk, and soon was running about and even walking long distances. The head smaller to appearance, became covered with a fine crop of healthy hair. Marked improvement in intelligence was seen in many little actions. The engraving from the second photograph shows the patient's

As regards small pox and vaccination we can measure results far more accurately, for although the intensity changes and climatic conditions are inconstant the course of events under the old and new order of things can be observed concurrently year by year and day by day, and it is this fact which makes the protective influence of vaccination perhaps the most clearly established of all points in preventive medicine. In every epidemic the two classes, the unprotected and the artificially protected, can be observed side by side, under like conditions. But even in regard to small pox the change of type has led to fallacy. At Leicester it has been alleged that with speedy isolation of persons attacked, and quarantine of those exposed to infection, small pox may be held in check, and that vaccination is unnecessary even if beneficial. The proof advanced is that small pox has not succeeded until lately in spreading amongst the imperfectly vaccinated population of Leicester. Many fallacies in this line of reasoning have long ago been pointed out. It ignores the assistance rendered by vaccination, even in Leicester. It presupposes early knowledge of all cases, however slight, compulsory isolation and quarantine, and the observance of a like thorough policy in all other localities, rural as well as urban. And further, if Leicester escaped because it had and used means of isolation and quarantine, how are we to account for the temporary escape of Keighley? A more probable explanation seems to be that the Leicester experiment with isolation and the Keighley experiment without it have only been tried during years of low intensity when small pox has scarcely been able to hold its ground in any part of England. Epidemic centres have been few, the chances of repeated importation comparatively small, and the power of diffusion slight. The real test has still to come, when the conditions are altered, as they seem likely to be within the next few years. It is not enough to introduce small pox amongst a population imperfectly protected by vaccination. That the recently vaccinated will not take small pox is certain, but it is not equally certain that the unprotected will at once be attacked. Something depends upon the quality of the small pox itself and it cannot safely be assumed that its power of epidemic spread is always the same, even if equal facilities be afforded.

Underlying all that mere death rates or even mere attack-rates can teach us there is a variable type of disease, only imperfectly shown by such records.

SUMMARY

1 Epidemic prevalence may be brought about either by increased potency of the disease itself or by increased mechanical facilities for diffusion.

2 Epidemics of the latter class, including water epidemics, milk epidemics and, as a rule, seasonal prevalence, are attended with lowered case mortality, because the conditions under which they occur imply a lessened average susceptibility and therefore a less severe average attack.

3 Underlying all great epidemics there is a change of epidemic type, a change in the quality of the disease itself.

4 There is evidence of a like change on a smaller scale in most, if not all, epidemic diseases, the intensity rising and falling at intervals which are not necessarily uniform for the same disease and are very different in different diseases.

5 Whether on the larger or smaller scale, the intensification is marked by greater severity of attack, greater power of overcoming comparative insusceptibility, and greater power of epidemic diffusion.

6 Whilst some diseases are capable of rapid or even abrupt changes in intensity, others are not, and this distinction serves to mark off broadly two principal groups, those which are mobile and those which are comparatively constant in type.

7 The first group, that of diseases which are capable of most rapid change in type, includes those which are most nearly allied to saprophytic life, most readily cultivated in artificial media, most dependent upon filthy conditions, most liable to infect soil, water, milk and lower animals, most liable to relapses, and least protective.

8 Diseases of this class may be highly modified, and some of them may assume and maintain a form so slight that their true character is unrecognised.

9 Under favourable conditions their intensity may slowly or suddenly increase, giving rise to epidemics of severer type.

10 Amongst diseases of this class an epidemic normally begins and ends with the milder forms, the more severe attacks occurring at the time of greatest prevalence. The severity and prevalence rise and fall together.

11 In the second group, amongst diseases of more fixed character extreme modification of epidemic type does not occur, but individual attacks may be extremely mild owing to high resistance.

12 Amongst such diseases there is evidence of a rise and fall of intensity if the epidemic course be traced for a term of years, perhaps covering several minor epidemics.

13 In these brief outbursts of diseases of more constant type there is little if any change of intensity comparable to that of the mobile class, the prevalence being determined and controlled mainly by external conditions, but the type being that of the prevailing phase of a broad cycle.

CRETINISM TREATED BY THE HYPODERMIC INJECTION OF THYROID EXTRACT AND BY FEEDING

BY EDWARD CARMICHAEL, M D EDIN & C.

ALTHOUGH several cases of myxœdema treated by thyroid extract and feeding have been reported, as also a case or two of cretinism by transplantation of the thyroid, few, if any, cases of the latter disease have been recorded as treated by the hypodermic injection of thyroid extract and feeding. I therefore desire to state briefly the following regarding a case which has been under my care. When first asked to see the patient some three years ago I found her very much as the engraving from the first photograph represents. Although between five and six years of age, she was like an infant, her features were broad and massive, her skin was dry and harsh, her abdomen prominent, the umbilicus protruding

or rather kept in position by plaster, the supra-clavicular pads of fat well marked, and the hair sparse, dry and unhealthy—as was remarked, “she had no hair at all.” She made no attempt to walk. Her intelligence was very feeble, although she recognised faces and was capable of showing affection towards her parents. Her appetite was extremely capricious, and if the nurse tried to give her a meal she did not care for it was immediately vomited. Obstinate constipation was present, relieved, however, by massage with castor oil. The temperature was always low, but on account of the difficulty of taking it I can give no consecutive table, on several occasions it was about 96° F, sometimes lower.

History.—The child from birth had been slow in action and in vital powers—e.g., vaccination was particularly

MAP OF CENTRAL ASIATIC RUSSIA

The dates indicate the occurrence of the first case of cholera. The dotted lines on the Caspian Sea mark the steamer routes, the length of time of crossing is marked against each route in hours. The total length of the Transcaspian Railway is 900 miles

Total for Asiatic Russia, without the Caucasus	89,175	46,831	—	—	52.5

* Calculated from the return of deaths, supposing a 50 per cent death rate.

From these figures it will be noted that the intensity of the cholera process, indicated by the proportion of fatal cases, has borne no constant relation to the intensity of the epidemic, as shown by the proportion of population attacked by the disease. Thus in Transcaspia, where out of every 100,000 inhabitants 400 suffered from cholera, 54 per cent. of the cases proved fatal, whilst in Tobolsk, where out of the same number of inhabitants 1865 persons, or nearly five times as many as in Transcaspia, suffered from the disease, only 48.4 per cent. of the cases succumbed. The extraordinarily high death rate of 70.5 in the Syr Daria province cannot but raise the suspicion that many cases which recovered have not been reported from this district.

I turn now to the measures taken by the Government and by the local authorities to prevent the spread of the epidemic. On Feb 28th the Ministry of the Interior received news of the existence of cholera in Herat, and, fearing its spread to Meshed, sent certain Russian physicians into Persia to watch the course of the disease and communicate its movements to the central authorities. Later on a Government order was issued to form a sanitary cordon along the Persian and Afghan frontiers, and as far as possible every one who passed them was subjected to a medical inspection and at once isolated if he showed any suspicious symptoms. At stations on the Transcaspian Railway accommodation was ordered to be prepared for the isolation of patients attacked in the trains. As soon as cholera was reported to be present in Meshed pilgrimages were ordered to be stopped, and a Russian physician was sent to Astrabad to concert measures with the Persian authorities in order to protect the frontier. These measures, however, proved futile, and the disease rapidly spread to Russian soil. Further efforts were made to check the epidemic, and a quarantine of seven days at Bala Ishem, the third station from the Caspian end of the railway, would, it was fondly hoped, prevent the disease spreading to the shores of the Caspian Sea, and so to European Russia. At the same time, since the large town of Ashkhabad received of necessity much of its food supply from the neighbouring province of Khorassan, a strict inspection of all grain, flour and dairy produce was ordered to be carried out at the frontier town of Gaudak. Measures were also taken beyond Samarcand at the eastern terminus of the line. At Tchinnaz, on the Syr Daria river, an "observation point" was established and provided with twenty beds under the charge of a doctor and three feldschers.¹ All passengers to Tashkent were examined here, and anyone with any gastro intestinal irregularity was forbidden to cross the river and was kept under observation. As

stated before, this measure also proved without avail, and Tashkent was affected on June 11th.

It may be noted that the Central Asian provinces are under the entire control of the Minister of War, and for all measures in this part of the country he alone is responsible. On the Caspian Sea the naval authorities are paramount, but the eastern coasts of this sea are under the military authorities, whilst for any measures concerning the southern or Persian shores the Foreign Minister has to concert with the Persian authorities, and on the western shores the co-operation of the Minister of War and of the Governor General of the Caucasus is necessary. For all matters concerning railroads and waterways the Minister of Ways and Communications is responsible, whilst regulations concerning the traffic of goods touch the domain of the Minister of Finance. Finally, a vast number of affairs relating to domestic organisation are under the control of the Minister of the Interior. From these various authorities, but more particularly from the Ministers of War, of Ways and Communications, and of the Interior, a number of detailed instructions were issued, which have since been collected and published in one volume, together with the more important regulations of recent years which still remain in force with regard to cholera. It has been stated in some English papers, with a recklessness not infrequent where Russia is concerned, that the measures taken by the authorities at St Petersburg were inefficient, and that they only "woke up to a sense of their responsibilities" when cholera was already within their borders. Anyone who reads impartially the circulars and instructions in this volume will see at once the groundlessness of these accusations. The danger of the introduction of cholera from Afghanistan or from Persia into Russian territory has long been recognised, and there are in constant force a number of orders and regulations for the prevention and treatment of the disease, not only amongst the troops, but also amongst the civil population,² whilst, as stated before, upon the first intimation of the existence of cholera in Herat, and later, upon its outbreak in Meshed, a series of important special measures was ordered to be carried out to prevent its passing the frontier. The fact that these measures did not prevent the introduction of the disease into the country must be explained rather by the possible failure of local agents to carry out the instructions, by the extreme difficulty of guarding a long land frontier, by the utter absence of hygiene or sanitation not only on the foreign side of the frontier but also amongst the population of the Russian territory, and finally by the nature of the country and its enormous distance from the central controlling authorities at St Petersburg. It might have been hoped that the Caspian Sea would prove a natural protective barrier for European Russia, and that strict measures of inspection, isolation and disinfection at ports around this sea would be as effective as similar measures have proved to be on the English coasts during the past summer.

This article may be appropriately closed by briefly relating the measures taken by the Russian authorities on the Caspian Sea. The order of the Ministry of the Interior of Sept. 12th, 1884, which insisted on fourteen days' quarantine on all ships coming to Russian ports from countries infected with cholera, was not acted on, but a new order was issued from the same authority on May 27th, 1892, which may be summarised as follows.—The three ports of Astrakhan, Baku and Oozoon Ada are the most important on the Caspian Sea and represent the north, west and east coasts respectively. Any case of cholera on a ship or in any port on the sea was ordered to be immediately reported to the Government authorities at each of these towns. The patient or patients were to be removed immediately to the nearest cholera hospital. Of such hospitals eleven either existed or were constructed at different ports around the sea—viz., Astrakhan, Lencorin, Baku, Petrovsk, Derbent, Gurief, Fort Alexandrovsk, Krasnovodsk, Oozoon Ada, Tchikhiljar and Astrakhan. All the belongings of the patients were ordered to be either thoroughly disinfected or burnt, and the ship with the passengers had to remain in

² The following are some of the orders in constant force. Prikaz of the War Department, April 27th 1885. Instructions as to the means of preventing and limiting the spread of cholera in the army and as to disinfection. Prikaz of the War Department, June 10th 1889. On the construction of cholera wards. Prikaz of the War Department Jan. 26th 1891. Instructions on the appearance of cholera in the army. From the Ministry of the Interior, Sept. 12th, 1884. Instructions for the sanitary control and cleansing of vessels coming from countries infected with cholera. From the Ministry of the Interior Feb. 13th 1889. Special regulations for Black Sea ports. From the Ministry of the Interior, Aug. 31st, 1890. Rules for the sanitary supervision of river navigation in times of cholera.

¹ A feldscher is a male attendant who has undergone a course of training in hospital. The full course extends over four years.

perineal route, a supra pubic opening affords better access to the tumour, gives more room for the necessary manipulations, and in cases where there is a deep perineum, contracted pelvis, or enlarged prostate it is the only method that is practicable. As a means of exploring the bladder in cases where the diagnosis is not certain respecting the simple or malignant nature of a growth, it also possesses great advantages, and if the growth is not removable and it is desirable simply to drain the bladder, as in Case 6, my experience of the two methods of drainage—supra pubic and perineal—is that the former is by far the most satisfactory, one advantage being that the opening in the vesical wall is made at a spot away from the seat of the disease, which, when of a malignant nature, usually affects the inferior fundus of the bladder.

Stone.—In six cases (Cases 3, 10, 11, 12, 15 and 16) the operation was performed for the removal of vesical calculi, and with the exception of one case (Case 3) all were successful. In this instance, again—one of my earliest supra pubic operations and, I may also add, the only case of lithotomy I have ever lost—the bladder wound was sutured. All went on satisfactorily for a few days, when the bladder began to leak

in a deep post-prostatic pouch. In one of these cases (Case 15), that of a patient under the care of Mr. Higginson of Bolton, I had four months previously attempted to perform lithotomy, but though a considerable portion of the stone was crushed and removed the operation was left uncompleted at the end of an hour the patient, who was an extremely stout subject, not bearing the anæsthetic at all well and beginning to show signs of collapse.

A question which naturally suggests itself is this: What are the indications for the selection of the supra pubic operation in cases of stone? Every surgeon will probably allow that, with the improved instruments which we now have, most calculi occurring in adults are capable of being removed by lithotomy, and I am myself of opinion that the same rule holds good in the case of children, my last six cases of stone in boys under ten years of age having been treated successfully by crushing. Up to the present time I have operated upon forty-two cases of calculus vesicæ (thirty-eight males and four females) and in the thirty-eight males lithotomy has been performed on seventeen and lithotomy on twenty-one occasions. In illustration of the fact that lithotomy has of late

and, the superficial wound having almost closed, the urine, being unable to escape externally, infiltrated the surrounding tissues setting up pelvic cellulitis, which proved fatal. This case taught me a lesson which has been of use—viz., never to attempt to procure primary union by suturing the opening in the bladder wall. In Case 10 the stone was of hard consistency and of large size, measuring over one inch and a half in diameter. In Case 11 that of a gentleman sent to me by Mr. Anderson of New Mills the symptoms were somewhat obscure. I had diagnosed a prostatic calculus on account of the excruciating pain and spasm of the neck of the bladder from which the patient suffered on attempts to micturate, which was so severe that he had passed no urine, except with a catheter, for more than two years. On opening the bladder a small stone was found lying loose in its interior whilst encysted in a small pouch the size of a walnut which was situated behind the prostate and communicated with the cavity of the bladder by a narrow neck: there was a collection of more small calculi. In Cases 12, 15 and 16 there was considerable enlargement of the prostate gland the calculi in each instance lying

years to a great extent superseded lithotomy, I may mention that, whereas in my first nineteen cases there were fifteen lithotomies and four lithotrities in my last nineteen cases, operated upon during the past three years, there were six lithotomies and thirteen lithotrities, a cutting operation only being performed when crushing was contraindicated by the size and hard nature of the stone, or by the fact that it was encysted or associated with considerable enlargement of the prostate gland. It is under these circumstances that the supra pubic method is indicated for I am of opinion that if a stone cannot be successfully crushed the same conditions are generally opposed to the performance of the lateral operation. In illustration of this fact I may refer again to my last five lithotomies all of which were supra pubic (Cases 10, 11, 12, 15 and 16) the conditions which were present, and which I have mentioned, precluding the successful performance either of lithotomy or lateral lithotomy. I believe that the days of lateral lithotomy, which I have only performed once in my last twenty-one operations for stone are numbered and that it will soon become an operation of the

quarantine for fourteen days and undergo a strict process of cleansing and disinfection. No vessel was permitted to carry passengers without having a medical man on board. If he declared the ship to be free from disease, and if on inspection all on board were found to be in good health, the ship was immediately allowed free *pratique*. Passengers were forbidden to take on board any dirty linen, clothes or bedding, these had to be washed, and if necessary disinfected. There are further instructions as to cleanliness on board and the disinfection of closets &c., rules for coasting vessels, arrangements as to the medical *personnel* of the cholera stations and for the provision of means for bacteriological investigation. It may be noted that in Russia there is complete acceptance of the proposition that cholera is due to the comma bacillus. One of the first circulars¹ issued contained a series of instructions as to the best means of staining and cultivating the bacillus, accompanied by photographic illustrations and a list of German authorities to be consulted on the subject. Early in June a number of Government and local measures were undertaken to prevent the epidemic spreading up the Volga and into the Caucasus. A considerable amount of activity was displayed by the authorities in Astrakhan and was conspicuous by its absence amongst the authorities in Baku, but these matters must be reserved for a second paper devoted to a consideration of the epidemic in the Caucasus.

STRANGULATED INGUINAL HERNIA (LEFT) IN AN INFANT AGED EIGHT MONTHS, OPERATION, COMPLI- CATION, RECOVERY

BY SURGEON CAPTAIN J. D. T. RECKITT,
M.R.C.S., L.R.C.P. EDIN. &c.

ON Dec 5th, 1892, at 11 A.M., I saw an infant aged eight months, the son of a soldier, having been attending it for several days before for broncho pneumonia, from which it was nearly convalescent. The child presented a pale and pinched countenance and was evidently suffering great pain. I was informed for the first time by the mother that the child had suffered from hernia since birth and that on this occasion the bowel had been down since 7 P.M. the night before. She also stated that though it had often been down before for several hours at a time she had never had any difficulty in replacing it. Vomiting had been going on at frequent intervals since 7 A.M. and the bowels had acted twice during the night. The hernial tumour was the size of a small Tangerine orange, very tight and painful on palpation, and with no impulse that I could detect when the child coughed or cried. I at once tried gentle taxis, but the manipulation did not seem to have the slightest effect. I then directed the mother to apply hot fomentations and, if that failed, to place the child in a hot bath, afterwards to keep it at rest in the recumbent position with the pelvis well raised. On account of the great pain and restlessness I ordered a sedative and stimulant mixture of compound spirit of ammonia and spirit of chloroform, with half a minim of tincture of opium every three hours, and I left, expecting that the means adopted would result in the return of the bowel, as I had often observed before in infants. However, at 2 P.M., when I called, there was no change, and taxis, as before, had no effect whatever. At 7 P.M. I myself placed the child in a hot bath, gave a four ounce enema of olive oil and again tried taxis, but to no purpose, and I then reluctantly decided (on account of the tender age and semi collapsed condition of the patient) to attempt relief by operation. At 10.30 P.M., aided by the best light that could be obtained at the parents' quarters, the child was placed under chloroform by Surgeon Captain O'Halloran of the Army Medical Staff, and, taxis again failing with both of us, I transfixed the integuments and laid open the sac. Though I could easily run my little finger all round the inside of the sac, I could not define clearly the neck or the external abdominal ring, and we had noticed that on opening the sac the usual amount of fluid did not escape. Though puzzled at the time, I made a small cut into a part of the next covering of the hernia, which I pinched up with dissecting forceps, with the result of

an immediate escape of the fluid previously looked for and on laying this sac open to the full extent of the wound I came across the bowel. The stricture was very tight and it was a matter of some difficulty with such a small patient to notch it, but this when done allowed the bowel (roughened in one or two places) to be easily returned. The light was not good enough to allow me to excise the sac, and though I cut away a little of it I did not care to persevere with the dissection, more particularly as I was troubled by the jumping up of the testis into the wound whenever I made traction with the forceps. The dangerous proximity and uncertain position, too, of the spermatic cord and vessels by such a light decided me to abandon the idea of a radical cure, and instead the edges of both sacs were drawn together along with the integuments by means of silver wire, and an iodoform and blue wool dressing was applied. The child slept at intervals during the nights of Dec 5th and 6th. There was no return of vomiting, and the bowels acted several times. The infant progressed without a bad symptom, the wound healed by first intention, and on Dec. 19th, a fortnight after herniotomy, it was quite well and was fitted with a truss.

Remarks.—I think this case is well worth reporting, the interesting features about it being, first, the tender age of the patient and, secondly, the existence of two sacs. I have not looked up the literature of the subject and therefore am ignorant of the experience others have had in children so young, but I myself have never been called upon to do herniotomy in a patient of such tender age, and I am told by Mr. Edmund Owen that he has not had to operate very frequently in very young children. The existence of two sacs was certainly puzzling with an indifferent artificial light, but it was of course readily explained on reference to the anatomy of the hernia, which was of the "infantile" variety. Shorncliffe, Kent.

ON THE INDICATIONS FOR SUPRA-PUBLIC CYSTOTOMY IN CASES OF TUMOUR, STONE, PROSTATIC RETENTION AND CYSTITIS¹

By F. A. SOUTHAM, M.B. OXON, F.R.C.S. ENG.,
SURGEON TO THE MANCHESTER ROYAL INFIRMARY

THE revival of the old "high operation" of opening the bladder, or "supra public cystotomy" as it is now termed, may be said to date from the year 1835, and the credit of its revival is mainly due to Sir Henry Thompson, who in that year performed it on seven occasions for the removal of calculi and tumours from the bladder. Since then it has been adopted by most surgeons, and at the present time it ranks as a recognised operation in the treatment of various forms of vesical disease. During the past seven years I have myself performed supra public cystotomy in seventeen cases, particulars of which are given in the following table, all the patients being of the male sex. A brief consideration of these cases, which may be arranged in four groups, according to the cause for which the operation was performed—viz., tumour, stone, prostatic retention of urine and cystitis—may perhaps be of interest, inasmuch as they illustrate the chief conditions in which supra public cystotomy is indicated.

Tumour.—In five cases (Cases 1, 2, 5, 6 and 13) the patients were the subjects of tumours of the bladder, and in four of these, where the growth was of a simple nature—viz., papilloma—removal was effected, twice successfully, twice with a fatal result. The two which proved unsuccessful were amongst my earliest cases—viz., the second and fifth occasions on which I performed this operation—and the fatal results were due to causes which a further experience in the technique and after treatment of supra public cystotomy has taught me are in a great measure preventable. The remaining case of tumour (Case 6) was one in which, the growth being of a malignant nature, no attempt was made to remove it, the bladder being drained through the supra public opening, with great relief to the patient's symptoms. For all cases of removal of vesical growths occurring in males there is no doubt that the supra public operation is far superior to perineal cystotomy. Though I have removed several tumours with success by the

gall stone, square or nearly so, and half an inch across in all directions. The wall of the duct around it was much thickened, but it did not completely obstruct it though there was very little space indeed for bile to flow by its side. The hepatic duct was much dilated, not so the cystic duct, through which the large stone must at one time have passed, though it was much reduced in length (quarter of an inch) and looked more like a foramen than a duct. The calculus had evidently not increased in size in the duct, as it was faceted on several sides. There was no trace of jaundice post mortem, and this lends to the clinical aspect of the case, the great interest of which lies in the fact that there had only been jaundice for nine days of very slight degree two years before her death, and that at that time there was no hepatic colic. Dr John Harley has very kindly communicated the fact that he had her under observation for twenty seven years—from 1864 to 1891—and that this was the only attack of jaundice she had manifested. During the last year of her life she had been under the observation of people who were intimate with her and they stated that she was never jaundiced, though during this period she had several attacks of severe abdominal pain, chiefly on the right side, with vomiting. Neither was there any history of the ague like paroxysms to which Dr Ostler has called attention as symptomatic of calculus impacted in the duct. The stone probably passed into the common duct at the time when she had the jaundice two years before her death but it is very remarkable how little obstruction was then present and how quickly and completely all the jaundice disappeared, the duct evidently rapidly dilating around the stone until almost directly after impaction had taken place room was made for the bile to flow past the side of it. And this is the more remarkable when it is remembered that the stone was one of considerable size.

It may be thought by some, on reading this report without an opportunity of examining the specimen, that possibly the secondary gall bladder was really a greatly distended cystic duct, but this was not so. It opened out of the gall bladder at the opposite side to the duct, and, moreover the fluid in the gall bladder was bile. The new cavity was evidently one formed by the adhesion of surrounding parts.

The tolerance of the peritoneum to extravasated bile is well illustrated by Thiersch's remarkable case (referred to in Mr Mayo Robson's book on Gall stones), in which he successfully removed many pints of bile from the abdominal cavity after the gall bladder had been ruptured by a blow, but that the peritoneum will not remain tolerant to bile for very long this case, amongst other, demonstrates.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL AND THERAPEUTICAL

CHLOROBROM IN MENTAL DISEASES

By JOHN KEAT M.D., F.R.C.P. EDIN.,
MEDICAL SUPERINTENDENT, MATERNITY ASYLUM, EDINBURGH.

THE excellent results obtained by the judicious use of the solution named "chlorobrom," introduced by Professor Charteris of Glasgow for the prevention and alleviation of sea sickness, have been recently recorded in the medical papers. I have not seen, however, any note of the solution having been used in the treatment of mental and nervous diseases; and as I have prescribed it in suitable cases in this asylum for about a year with results which seem to show that in it we have a valuable addition to our still too short list of really safe and reliable hypnotics I may perhaps be allowed to state my experience very briefly. As a general sedative in various forms of maniacal excitement in the excitement of general paralysis and of epilepsy, I have tried chlorobrom without sufficiently encouraging results to warrant perseverance. In such cases when it is found necessary to use a sedative I find sulphonal or the bromides (alone or in combination with cannabis indica) much more efficient and equally safe. As a hypnotic, however, in melancholia and allied mental conditions I have found chlorobrom reliable pleasant to take, and free from risk

and from disagreeable after effects. In the threatened melancholia brain exhaustion, or breakdown so commonly occurring in overworked and worried business men, insomnia is usually such an obstinate and painful symptom that the use of a hypnotic cannot be avoided. In some cases the drug which has been of late, perhaps, most in favour is paraldehyde, and it is safe, reliable, and seldom followed by unpleasant sensations. It has, however, a most disagreeable taste, which cannot be disguised, and it imparts to the breath an enduring and most objectionable odour. Instead of paraldehyde, therefore, I now prescribe an ounce of chlorobrom to be taken an hour before retiring to rest. I find that a sound sleep, lasting from six to eight hours, is almost invariably produced, that it is not followed by sickness, headache, or lassitude next morning, that the stomach and bowels are not deranged, and that there is no impairment of nutrition even when the drug is given regularly for weeks. A patient at present under my care has increased more than a stone in weight whilst taking a regular nightly dose. Another form of mental depression in which I have found chlorobrom valuable is the excited, or motor, variety of melancholia. In cases of this kind paraldehyde is sometimes quite useless, in fact, unless given in large doses it may even increase the excitement. Chlorobrom has no such tendency. It combines the sedative with the purely hypnotic action and acts somewhat like paraldehyde when given along with bromidia or one of the bromides. An ounce of the solution may be given an hour before bedtime. When the excitement is considerable a larger dose may be required and may be given without fear—say, an ounce and a half or two ounces. I have never known unpleasant results to follow. In the other forms of melancholia one is not so frequently driven to the use of hypnotics, but in their treatment, also, my experience of chlorobrom has been favourable, and I intend to use it in future as suitable cases present themselves.

As mentioned above, one ounce is a medium hypnotic dose of chlorobrom, representing thirty grains of chloralamid and thirty grains of bromide of potassium. The full effect is generally produced about an hour after administration. It is not objected to by patients and is swallowed without difficulty, its taste and smell being quite pleasant. In this respect it compares most favourably with paraldehyde, and ease of administration is a matter of no small moment when dealing with insane or nervous patients. Chlorobrom has no disagreeable after effects. It does not interfere with nutrition. It does not interfere with the restoration of the normal sleep habit, and its discontinuance has not been followed, so far as I have observed, by any morbid craving.

MALIGNANT DISEASE OF THE PROSTATE

By WORSLEY J. HARRIS, L.R.C.P. LOND &c

THE patient was a small, thin, wiry man aged sixty five, who first consulted me at the end of November, 1891, for (1) frequency of micturition, (2) pain of a dull, aching character in the perineum, (3) pain along the urethra and at the end of the penis, (4) some difficulty of micturition. All these symptoms came on three weeks previously, and he had never had any trouble before then. On examination per rectum the middle lobe of the prostate showed decided enlargement. The sound in the bladder detected no stone. A prostatic curved silver catheter passed much more easily than the ordinary one. The patient was given a soft catheter and taught to use it himself. Thus he did on and off for some three weeks. Then he seemed to give up all hope and took to his bed, and nothing would induce him to help himself. He was thoroughly examined, but no organic mischief was found in any of his other organs. Up to February 1892, he remained at a standstill, but in the beginning of that month all the symptoms of pain—increased difficulty and frequency of micturition, rectal pain and constipation and general emaciation—became more marked. The prostate increased rapidly in size and some hæmaturia occurred occasionally. All these symptoms increased during February, March, April and May. The inguinal glands began to enlarge, and hard nodules were felt in the pelvis per rectum. The bowels were only relieved by enemata. The bladder was very contracted and urine constantly voided, but there was never any retention beyond about an ounce, which when drawn off consisted mostly of pus. The patient gradually sank and died of asthenia, quietly passing away on May 28th (seven months

past, for if a stone cannot be crushed it will be most safely removed through a supra pubic opening, the one essential for success being a condition of the bladder which will allow of its moderate distension with fluid. In children under ten years of age I have twice crushed uric acid calculi one inch and a quarter in diameter, but if the stone exceeds this size supra pubic lithotomy is indicated, and, as a rule, the larger and harder the stone and the younger the patient, the greater is the reason for selecting this operation. In adults a uric acid or oxalate of lime calculus one inch and a half in diameter or upwards is best removed by the supra pubic operation, especially if there is any enlargement of the prostate gland. In cases where there is any suspicion or evidence of chronic renal disease and the patient is advanced in years and probably the subject of hypertrophy of the prostate, I believe that a rapidly performed supra pubic lithotomy is attended by much less risk than a protracted crushing operation. The only case of lithotomy I have so far lost was performed under these conditions. A gouty gentleman seventy-two years of age (a patient of Dr Sellers of Radcliffe) had an enlarged prostate and probably granular kidneys, the stone was of roundish shape and about an inch in diameter, consisting of uric acid, the operation, which lasted an hour, was rendered extremely difficult by the fact that the stone lay in a deep post-prostatic pouch. He suffered severely afterwards from shock, developed uræmic symptoms and, becoming comatose, died on the following day. I have regretted since that in this instance I did not perform supra pubic lithotomy instead of lithotomy.

Retention of urine.—In five cases the operation was undertaken for the relief of prostatic retention of urine, which in two instances (Cases 7 and 14) had come on somewhat suddenly. In Case 7, seen in consultation with Mr De Jong and Mr Ferriday, there was a huge malignant growth connected with the prostate gland, which rendered catheterism quite impossible. In Case 14, where there was an enlarged prostate and also a stricture, the bladder was distended with blood clot, the result of unsuccessful attempts at catheterism previously to admission into hospital, and the clots were so firm that it would have been impossible to have removed them through a catheter, even if one could have been introduced into the bladder. In the other cases (Cases 8, 9 and 17) the retention, which was due to simple enlargement of the prostate, had been present for some time and was capable of being relieved by catheterism. In Cases 8 and 9 the operation was undertaken with the idea of removing the cause of obstruction to the escape of the urine, and the excision in one instance of a portion of the prostate and its vertical section in the other was followed by a return of the power of voluntary micturition. In Case 17, seen in consultation with Dr Saul, the retention was accompanied by very profuse bleeding from the prostate, and it was mainly with the idea of arresting the hæmorrhage that the bladder was opened, as it appeared certain that unless some active treatment was undertaken the patient would soon sink from loss of blood. It was interesting to note that the bleeding, which previously could not be stopped by the ordinary means, completely ceased after the operation, no doubt because the free drainage, by preventing straining and thus by keeping the bladder in a state of rest, at once relieved the congestion of the prostate to which the hæmorrhage was due. As regards the class of cases of retention in which supra pubic cystotomy should be performed, I am of opinion that it is indicated in habitual retention due to enlargement of the prostate. First, when palliative treatment—viz., regularly drawing off the urine and washing out the bladder—has failed to give relief, and when self catheterism is impracticable or attended by pain (Cases 8 and 9), and secondly, when the retention is accompanied by active hæmorrhage into the interior of the bladder, which cannot be checked by ordinary means (Case 17). Under these circumstances the operation enables one of the following courses to be adopted—(1) Free drainage for a time, which is often followed by a return of the power of voluntary micturition, (2) permanent drainage by the establishment of a supra pubic fistula, and (3) removal or division of the obstructing portion of the prostate gland.

Cystitis.—Another class of cases in which supra pubic cystotomy is sometimes required is in severe or obstinate cases of chronic cystitis, and especially in the tubercular form when accompanied by ulceration. Here the operation is not only useful as a means of effectually draining and irrigating the bladder, but it also affords access to the ulcers, which may

be scraped or cauterised. I have only once had occasion to perform the operation in a case of this kind (Case 4). The patient, who was the subject of advanced general tuberculosis, in addition to the usual symptoms of cystitis, suffered from hæmaturia and also from great pain and difficulty in micturition, owing to the obstruction caused by the presence of extensive tuberculous deposits in both seminal vesicles. The operation was followed by immediate relief, but the patient, who was in an extremely exhausted state at the time of its performance, sank on the following day.

In conclusion, I would draw attention to the fact that, whereas of the first seven cases five were fatal, the last ten have all been successful. In two of the fatal cases (Cases 4 and 7) death can hardly be attributed to the operation, as both patients were in a hopeless condition. In the other three cases (Cases 2, 3 and 5) the fatal results were due to septicæmia, pelvic cellulitis and peritonitis—complications which are, I believe, now almost certainly preventable if during the operation the cellular tissue in front of the bladder is not much disturbed and if during the after treatment the wound is kept in an aseptic condition by frequently dousing it with boric acid and by washing out the bladder with boric lotion. As already stated, I am of opinion that the opening in the bladder should never be sutured, it adds a danger to the operation, for if the bladder begins to leak after the superficial wound has entirely or partly closed (as in Case 3) extravasation of urine and pelvic cellulitis are very likely to occur. If, on the other hand, the suturing is successful, the operation is deprived of one of its chief advantages—viz., the free after drainage, which is always beneficial.

Manchester

A CASE OF PRIMARY PERFORATION OF THE GALL-BLADDER,

WITH THE FORMATION OF AN ADDITIONAL CAVITY UNDER THE SURROUNDING ADHESIONS, SECONDARY RUPTURE OF THIS CAVITY INTO THE PERITONEUM, IMPACTION OF STONE IN COMMON DUCT WITHOUT JAUNDICE

BY CHARLES A. MORTON F.R.C.S. ENG.,
REGISTRAR TO THE BRISTOL GENERAL HOSPITAL, PATHOLOGIST TO THE BRISTOL CHILDREN'S HOSPITAL.

I SHALL first describe what I discovered at the post-mortem examination and afterwards refer to the symptoms which, in the light of the necropsy, are of considerable interest. I am much indebted to Mr L. M. Griffiths of Clifton for inviting me to make the necropsy and for allowing me to show the specimen at our local medical society and to publish this report of it. The patient, a woman aged sixty, was under the care of Mr L. M. Griffiths and I did not see her during life. She died on Nov. 22nd, 1892, and on the 23rd I made the post-mortem examination. The body was well nourished. The abdomen was distended and on opening it much orange-coloured fluid escaped and general recent adhesive peritonitis was discovered. Just below the liver was a cavity the size of an orange, bounded above by the under surface of the liver, and in front by the thin margin of the liver and the omentum, which had been adherent to it. Below, it was separated from the colon by much thickened tissue. On its inner side lay the omentum, and on its outer side, covered by adhesions between the liver and adjacent parts lay the gall bladder, which opened into the cavity, by an aperture which would admit one or two fingers. The wall of the gall bladder was much thickened and several stones half an inch in diameter were found lying in it. Where the omentum had before been adherent to the anterior edge of the liver, forming the anterior wall of the cavity, it had become detached, and thus the bile had escaped into the peritoneum and set up fatal peritonitis. No doubt at one time the gall bladder, containing gall stones, had perforated under these surrounding adhesions, and thus the secondary gall bladder had been formed, which in its turn, had finally ruptured into the peritoneum. The old gall bladder was not dilated to any extent.

The formation of this secondary gall bladder is not the only point of interest in the pathology of the case. In the common duct, just after the cystic and hepatic ducts join (and where Mr Mayo Robson states there is normally a slight dilatation, so that stones are apt to lodge), was another

gall stone, square or nearly so, and half an inch across in all directions. The wall of the duct around it was much thickened, but it did not completely obstruct it, though there was very little space indeed for bile to flow by its side. The hepatic duct was much dilated, not so the cystic duct, through which the large stone must at one time have passed, though it was much reduced in length (quarter of an inch) and looked more like a foramen than a duct. The calculus had evidently not increased in size in the duct as it was faceted on several sides. There was no trace of jaundice post mortem, and this lends to the clinical aspect of the case, the great interest of which lies in the fact that there had only been jaundice for nine days of very slight degree two years before her death, and that at that time there was no hepatic colic. Dr John Harlev has very kindly communicated the fact that he had her under observation for twenty-seven years—from 1864 to 1891—and that this was the only attack of jaundice she had manifested. During the last year of her life she had been under the observation of people who were intimate with her and they stated that she was never jaundiced, though during this period she had several attacks of severe abdominal pain, chiefly on the right side, with vomiting. Neither was there any history of the ague-like paroxysms to which Dr O'tter has called attention as symptomatic of calculus impacted in the duct. The stone probably passed into the common duct at the time when she had the jaundice two years before her death, but it is very remarkable how little obstruction was then present and how quickly and completely all the jaundice disappeared, the duct evidently rapidly dilating around the stone until almost directly after impaction had taken place room was made for the bile to flow past the side of it. And this is the more remarkable when it is remembered that the stone was one of considerable size.

It may be thought by some, on reading this report without an opportunity of examining the specimen, that possibly the secondary gall bladder was really a greatly distended cystic duct, but this was no so. It opened out of the gall bladder at the opposite side to the duct, and, moreover, the fluid in the gall bladder was bile. The new cavity was evidently one formed by the adhesion of surrounding parts.

The tolerance of the peritoneum to extravasated bile is well illustrated by Thierch's remarkable case (referred to in Mr Mayo Robson's book on Gall stones) in which he successfully removed many pints of bile from the abdominal cavity after the gall bladder had been ruptured by a blow, but that the peritoneum will not remain tolerant to bile for very long in this case, amongst other, demonstrates.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL AND THERAPEUTICAL.

CHLOROBROM IN MENTAL DISEASES

By JOHN KEAY M.D., F.R.C.P. EDIN.

MEDICAL SUPERINTENDENT, MATHIASANE ASYLUM, EDINBURGH.

THE excellent results obtained by the judicious use of the solution named "chlorobrom," introduced by Professor Charters of Glasgow for the prevention and alleviation of sea sickness, have been recently recorded in the medical papers. I have not seen, however, any note of the solution having been used in the treatment of mental and nervous diseases and as I have prescribed it in suitable cases in this asylum for about a year with results which seem to show that in it we have a valuable addition to our still too short list of really safe and reliable hypnotics I may perhaps be allowed to state my experience very briefly. As a general sedative in various forms of maniacal excitement, in the excitement of general paralysis and of epilepsy I have tried chlorobrom without sufficiently encouraging results to warrant perseverance. In such cases, when it is found necessary to use a sedative, I find sulphonal or the bromides (alone or in combination with cannabina indica) much more efficient and equally safe. As a hypnotic, however, in melancholia and allied mental conditions I have found chlorobrom reliable, pleasant to take, and free from risk

and from disagreeable after effects. In the threatened melancholia brain exhaustion, or breakdown so commonly occurring in overworked and worried business men, insomnia is usually such an obstinate and painful symptom that the use of a hypnotic cannot be avoided. In some cases the drug which has been of late, perhaps most in favour is paraldehyde and it is safe, reliable, and seldom followed by unpleasant sensations. It has, however, a most disagreeable taste which cannot be disguised, and it imparts to the breath an enduring and most objectionable odour. Instead of paraldehyde, therefore I now prescribe an ounce of chlorobrom to be taken an hour before retiring to rest. I find that a sound sleep, lasting from six to eight hours, is almost invariably produced, that it is not followed by sickness headache or lassitude next morning, that the stomach and bowels are not deranged, and that there is no impairment of nutrition even when the drug is given regularly for weeks. A patient at present under my care has increased more than a stone in weight whilst taking a regular nightly dose. Another form of mental depression in which I have found chlorobrom valuable is the excited or motor variety of melancholia. In cases of this kind paraldehyde is sometimes quite useless, in fact, unless given in large doses it may even increase the excitement. Chlorobrom has no such tendency. It combines the sedative with the purely hypnotic action and acts somewhat like paraldehyde when given along with bromidia or one of the bromides. An ounce of the solution may be given an hour before bedtime. When the excitement is considerable a larger dose may be required and may be given without fear—say an ounce and a half or two ounces. I have never known unpleasant results to follow. In the other forms of hypnotics but in their treatment also my experience of chlorobrom has been favourable, and I intend to use it in future as suitable cases present themselves.

As mentioned above, one ounce is a medium hypnotic dose of chlorobrom, representing thirty grains of chloralamid and thirty grains of bromide of potassium. The full effect is generally produced about an hour after administration. It is not objected to by patients and is swallowed without difficulty, its taste and smell being quite pleasant. In this respect it compares most favourably with paraldehyde, and ease of administration is a matter of no small moment when dealing with insane or nervous patients. Chlorobrom has no disagreeable after effects. It does not interfere with nutrition. It does not interfere with the restoration of the normal sleep habit, and its discontinuance has not been followed, so far as I have observed, by any morbid craving.

MALIGNANT DISEASE OF THE PROSTATE.

By WORSLEY J. HARRIS, L.R.C.P. LOND. &c.

THE patient was a small, thin, wiry man aged sixty five, who first consulted me at the end of November, 1891, for (1) frequency of micturition, (2) pain of a dull, aching character in the perineum, (3) pain along the urethra and at the end of the penis, (4) some difficulty of micturition. All these symptoms came on three weeks previously and he had never had any trouble before then. On examination per rectum the middle lobe of the prostate showed decided enlargement. The sound in the bladder detected no stone. A prostatic curved silver catheter passed much more easily than the ordinary one. The patient was given a soft catheter and taught to use it himself. This he did on and off for some three weeks. Then he seemed to give up all hope and took to his bed, and nothing would induce him to help himself. He was thoroughly examined but no organic mischief was found in any of his other organs. Up to February 1892, he remained at a standstill, but in the beginning of that month all the symptoms of pain—increased difficulty and frequency of micturition, rectal pain and constipation and general emaciation—became more marked. The prostate increased rapidly in size and some hæmaturia occurred occasionally. All these symptoms increased during February, March, April and May. The inguinal glands began to enlarge, and hard nodules were felt in the pelvis per rectum. The bowels were only relieved by enemata. The bladder was very contracted and urine constantly voided but there was never any retention beyond about an ounce, which when drawn off consisted mostly of pus. The patient gradually sank and died of asthenia, quietly passing away on May 28th (seven months

past, for if a stone cannot be crushed it will be most safely removed through a supra pubic opening, the one essential for success being a condition of the bladder which will allow of its moderate distension with fluid. In children under ten years of age I have twice crushed uric acid calculi one inch and a quarter in diameter, but if the stone exceeds this size supra pubic lithotomy is indicated, and, as a rule, the larger and harder the stone and the younger the patient, the greater is the reason for selecting this operation. In adults a uric acid or oxalate of lime calculus one inch and a half in diameter or upwards is best removed by the supra pubic operation, especially if there is any enlargement of the prostate gland. In cases where there is any suspicion or evidence of chronic renal disease and the patient is advanced in years and probably the subject of hypertrophy of the prostate, I believe that a rapidly performed supra pubic lithotomy is attended by much less risk than a protracted crushing operation. The only case of lithotomy I have so far lost was performed under these conditions. A gouty gentleman seventy-two years of age (a patient of Dr Sellers of Radcliffe) had an enlarged prostate and probably granular kidneys, the stone was of roundish shape and about an inch in diameter, consisting of uric acid, the operation, which lasted an hour, was rendered extremely difficult by the fact that the stone lay in a deep post-prostatic pouch. He suffered severely afterwards from shock, developed uræmic symptoms and, becoming comatose, died on the following day. I have regretted since that in this instance I did not perform supra pubic lithotomy instead of lithotomy.

Retention of urine.—In five cases the operation was undertaken for the relief of prostatic retention of urine, which in two instances (Cases 7 and 14) had come on somewhat suddenly. In Case 7, seen in consultation with Mr De Jong and Mr Ferriday, there was a huge malignant growth connected with the prostate gland, which rendered catheterism quite impossible. In Case 14, where there was an enlarged prostate and also a stricture, the bladder was distended with blood clot, the result of unsuccessful attempts at catheterism previously to admission into hospital, and the clots were so firm that it would have been impossible to have removed them through a catheter, even if one could have been introduced into the bladder. In the other cases (Cases 8, 9 and 17) the retention, which was due to simple enlargement of the prostate, had been present for some time and was capable of being relieved by catheterism. In Cases 8 and 9 the operation was undertaken with the idea of removing the cause of obstruction to the escape of the urine, and the excision in one instance of a portion of the prostate and its vertical section in the other was followed by a return of the power of voluntary micturition. In Case 17, seen in consultation with Dr Saul, the retention was accompanied by very profuse bleeding from the prostate, and it was mainly with the idea of arresting the hæmorrhage that the bladder was opened, as it appeared certain that unless some active treatment was undertaken the patient would soon sink from loss of blood. It was interesting to note that the bleeding, which previously could not be stopped by the ordinary means, completely ceased after the operation, no doubt because the free drainage, by preventing straining and thus by keeping the bladder in a state of rest, at once relieved the congestion of the prostate to which the hæmorrhage was due. As regards the class of cases of retention in which supra pubic cystotomy should be performed, I am of opinion that it is indicated in habitual retention due to enlargement of the prostate. First, when palliative treatment—viz., regularly drawing off the urine and washing out the bladder—has failed to give relief, and when self catheterism is impracticable or attended by pain (Cases 8 and 9), and secondly, when the retention is accompanied by active hæmorrhage into the interior of the bladder, which cannot be checked by ordinary means (Case 17). Under these circumstances the operation enables one of the following courses to be adopted—(1) Free drainage for a time, which is often followed by a return of the power of voluntary micturition, (2) permanent drainage by the establishment of a supra pubic fistula, and (3) removal or division of the obstructing portion of the prostate gland.

Cystitis.—Another class of cases in which supra pubic cystotomy is sometimes required is in severe or obstinate cases of chronic cystitis, and especially in the tubercular form when accompanied by ulceration. Here the operation is not only useful as a means of effectually draining and irrigating the bladder, but it also affords access to the ulcers, which may

be scraped or cauterised. I have only once had occasion to perform the operation in a case of this kind (Case 4). The patient, who was the subject of advanced general tuberculosis, in addition to the usual symptoms of cystitis, suffered from hæmaturia and also from great pain and difficulty in micturition, owing to the obstruction caused by the presence of extensive tuberculous deposits in both seminal vesicles. The operation was followed by immediate relief, but the patient, who was in an extremely exhausted state at the time of its performance, sank on the following day.

In conclusion, I would draw attention to the fact that, whereas of the first seven cases five were fatal, the last ten have all been successful. In two of the fatal cases (Cases 4 and 7) death can hardly be attributed to the operation, as both patients were in a hopeless condition. In the other three cases (Cases 2, 3 and 5) the fatal results were due to septicæmia, pelvic cellulitis and peritonitis—complications which are, I believe, now almost certainly preventable if during the operation the cellular tissue in front of the bladder is not much disturbed and if during the after treatment the wound is kept in an aseptic condition by frequently dusting it with boric acid and by washing out the bladder with boric lotion. As already stated, I am of opinion that the opening in the bladder should never be sutured, it adds a danger to the operation, for if the bladder begins to leak after the superficial wound has entirely or partly closed (as in Case 3) extravasation of urine and pelvic cellulitis are very likely to occur. If, on the other hand, the suturing is successful, the operation is deprived of one of its chief advantages—viz., the free after drainage, which is always beneficial.

A CASE OF PRIMARY PERFORATION OF THE GALL-BLADDER,

WITH THE FORMATION OF AN ADDITIONAL CAVITY UNDER THE SURROUNDING ADHESIONS, SECONDARY RUPTURE OF THIS CAVITY INTO THE PERITONEUM, IMPACTION OF STONE IN COMMON DUCT WITHOUT JAUNDICE.

By CHARLES A MORTON, F.R.C.S. Eng.,
REGISTRAR TO THE BRISTOL GENERAL HOSPITAL, PATHOLOGIST TO THE BRISTOL CHILDREN'S HOSPITAL.

I SHALL first describe what I discovered at the post-mortem examination and afterwards refer to the symptoms which, in the light of the necropsy, are of considerable interest. I am much indebted to Mr L M Griffiths of Clifton for inviting me to make the necropsy and for allowing me to show the specimen at our local medical society and to publish this report of it. The patient, a woman aged sixty, was under the care of Mr L M Griffiths and I did not see her during life. She died on Nov 22nd, 1892, and on the 23rd I made the post-mortem examination. The body was well nourished. The abdomen was distended and on opening it much orange coloured fluid escaped and general recent adhesive peritonitis was discovered. Just below the liver was a cavity the size of an orange, bounded above by the under surface of the liver, and in front by the thin margin of the liver and the omentum, which had been adherent to it. Below, it was separated from the colon by much thickened tissue. On its inner side lay the omentum, and on its outer side, covered by adhesions between the liver and adjacent parts, lay the gall bladder which opened into the cavity, by an aperture which would admit one or two fingers. The wall of the gall bladder was much thickened and several stones half an inch in diameter were found lying in it. Where the omentum had before been adherent to the anterior edge of the liver, forming the anterior wall of the cavity, it had become detached, and thus the bile had escaped into the peritoneum and set up fatal peritonitis. No doubt at one time the gall bladder, containing gall stones, had perforated under these surrounding adhesions, and thus the secondary gall bladder had been formed, which in its turn, had finally ruptured into the peritoneum. The old gall bladder was not dilated to any extent.

The formation of this secondary gall bladder is not the only point of interest in the pathology of the case. In the common duct just after the cystic and hepatic ducts join (and where Mr Mayo Robson states there is normally a slight dilatation, so that stones are apt to lodge), was another

from the loop that presented in the wound and passing the intestine through the fingers just within the wound in lengths of about three inches, returning one portion before the next was brought into view. Before three feet of intestine had been thus examined Mr Marsh found that the part he was approaching was fixed so that it could not be drawn forwards. On following this portion a band of the size of a No 4 catheter, apparently connected with the mesentery and tightly constricting the gut, was reached. Before it could be exposed, however, it gave way. The intestine was now quite free, and when drawn forwards it presented upon its wall, just where the distended and the constricted segments met, a round cord like band of the size mentioned above, about two inches long and apparently consisting of soft fibrous tissue, as if an inflammatory adhesion had become organised. The band was ligatured close to the intestine and removed. No further obstruction could be found, and as the bowel, though deeply marked by the constriction, was not ulcerated, it was returned and the abdominal cavity was irrigated with iodine water (1 in 500 of the tincture in water, at a temperature of 95°) and the wound closed. The symptoms of obstruction at once disappeared, sickness ceased, flatus was freely passed and the bowels acted naturally on the following day (Oct. 31st). On Nov 1st a large evacuation was passed. The wound healed by primary union. Nutritive enemata were given and the boy was allowed for the first forty eight hours to swallow nothing but water in teaspoonful doses every two hours. He complained of severe thirst, and on Nov 2nd seventy two hours after the operation and during the momentary absence of the nurse from the room, he got out of bed, climbed over the next bed and drank a tumblerful of water belonging to another boy, and was rapidly making his way back when the nurse returned. This exploit was fortunately not followed by any bad result, and a fortnight later he went to his home in the country.

Remarks by Mr HOWARD MARSH—In this case there are two points of some interest. 1. The gradual manner in which the symptoms were developed, and the time, five days, which elapsed before they were pronounced enough to call for operative interference were features but very seldom met with in obstruction of the small intestine by a band. Usually the symptoms are acute and of rapidly increasing severity, but up to the middle of the fifth day this patient looked as if he ailed very little, and the occurrence of fecal vomiting was somewhat of a surprise to those who were watching the case. The explanation no doubt was that as the band was a long one complete obstruction was only slowly produced. 2. The relief afforded by the division of the band was immediate and entire, the bowels acted spontaneously in a few hours, and the boy as the result showed, was practically well as soon as the operation was completed. The laparotomy was of the simplest kind, and was as well borne as an operation for hernia.

HOPE HOSPITAL, WARRINGTON

A CASE OF ERUPTION RESEMBLING THAT OF VARIOLA, REMARKS

(Under the care of Mr GORNALL.)

A CASE has recently come under the care of Mr Gornall which, while presenting features of difficulty in diagnosis, has, at the same time, afforded an excellent opportunity of putting to the test the opinion which was formed as to its real character.

A fine healthy girl, four years old, was notified as suffering from small pox and admitted into the Hope Hospital at Warrington on Jan. 7th. The facts as to the previous history of the illness which were known at the time, were not sufficient to warrant action upon the doubts which were entertained, while the condition found on examining her afforded an additional reason for detaining her. It may be said that there is no isolation ward for dubious cases. No cicatrices of vaccination could be found and it was gathered that her parents were opposed to the practice and lived in one of the great centres of the anti vaccination movement, from which place the child had recently come to stay with some relatives in Warrington. The spots had been out several days and had been preceded by considerable constitutional disturbance, in connexion with which pain in the back and chest was described. On admission to hospital the child appeared not to be in any way ill,

her temperature was normal, her appetite, though slightly impaired through soreness of the throat, became in a day or two excellent, she had on the forehead the dried scabs of three pocks and a few on the scalp in a similar state, while on the body there was a considerable eruption. This consisted of about fourteen spots on the front of the body and thirty on the back, the limbs were entirely free from them. The pocks, which were in the suppurative stage, presented a red inflammatory areola surmounted by, in the great majority of cases, a flat vesicle having a most typical umbilication, and could in no way be distinguished from small pox, in a few there was a more acuminate form. Examination of the throat revealed nothing more than slight erythema. The case was undoubtedly a suspicious one, though its mildness was quite opposed to Mr Gornall's experience of small pox in unvaccinated children, and after further consideration it was determined to vaccinate the patient. This was done with calf lymph by four insertions on the left arm thirty six hours after admission, and two days afterwards again by one insertion on the right arm. The result was the development of typical vaccinia (the less marked, of course in the case of the latter insertion) which has run a protracted and somewhat severe course, though the child has remained all along, except for the temporary constitutional disturbance caused by this, in excellent health. She was three weeks after admission free from any untoward symptom. The original eruption rapidly dried up and no fresh spots developed.

Remarks by Mr GORNALL—I have no doubt it was a case of chicken pox, and what I have since been able to glean from the medical attendant and relatives adds some confirmation to this opinion, though showing a case with somewhat unusual features. The child came to Warrington on Dec 28th. She remained well till the evening of Jan. 2nd, when she became sick and vomited, complaining of pain in the back. On the morning of Jan. 3rd she seemed brighter, but two spots were noticed on her neck, which soon developed a "humourous head." During that day she was quite well enough to go out and had a good appetite. On Jan 4th she was all right till towards midday, when she became languid and again complained of pain in the back, and was now found to be covered with spots which had certainly not been there the previous night, they, like the others soon became vesiculate. On Jan 5th no fresh spots had developed, but the child was restless, complaining of pain in the head and throat, which in the case of the latter interfered with swallowing. On Jan 6th the throat continued very sore and the child was restless at night. The case was definitely pronounced by the medical attendant to be small pox and she was removed the following day to the Hope Hospital. I have subsequently through the kindness of the medical officer of health of the locality from which the child came, been able to ascertain that her sister has recently been suffering from chicken pox, and that there have been other cases of the same disease in the neighbourhood of her home, but no small pox in the locality. This throws an interesting light on a complaint which, whether it was variola or varicella, must have been contracted before coming to Warrington.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY

Fibrous Polypus of Prostatic Urethra—Etiology of R6theln.

AN ordinary meeting of this Society was held on March 14th, the President, Sir Andrew Clark, in the chair.

Mr BRYANT read a paper on a case of Fibrous Polypus of the Prostatic Portion of the Urethra associated with Profuse Hematuria and Prostatic Enlargement, in which removal of the growth was followed by recovery. The case was that of a gentleman aged sixty three who had suffered from hematuria for six years, which was at times very profuse. When seen he was collapsed from loss of blood and suffering from retention of urine, with an enormously enlarged prostate. Temporary relief was afforded by catheterism, an exploratory median perineal operation was performed a few days later. At the operation no disease was discovered in the bladder nor any enlargement of the vesical lobe of the prostate gland. The gland otherwise was much enlarged and felt

after the first uræmic signs), never having had any delirium or comatose symptoms

Necropsy.—This was imperfect, as only the tumour was allowed to be removed. This and the bladder, with some lumbar glands, were removed, and with much difficulty, as the growth was extremely adherent to the adjacent structures. The growth was found on examination after removal to surround all the lower half of the bladder, the ureters, vesiculae seminales, vasa deferentia, spermatic cord, and the membranous portion of the urethra, and to be pressing on the rectum. The inguinal and lumbar glands were all enlarged and hardened. The growth appeared as an enormous enlargement of the whole of the prostate.

Microscopical examination.—Sections of the tumour, stained with logwood and mounted in Canada balsam, showed as chief characteristics a great growth of fibrous tissue appearing in wavy bundles and running in various directions, whilst at some places there were collections of cells the outlines of which were indefinite, but which were mostly small round cells, and these were commencing to infiltrate the growth.

Remarks.—I have thought it worth while to publish this case, as "malignant disease of the prostate" is a rare affection, especially "primary" malignancy of that organ. I regret that the other organs could not be examined, but the primary character of the case is shown by no symptoms being referable to, and nothing abnormal being detected during life in, any other organ except the prostate. Clinically, the extreme malignancy of the growth is proved by the rapid emaciation of the patient, the quick enlargement of the growth, and the occurrence of metastatic enlargement of the inguinal and lumbar glands, and pathologically it is shown by the great irregularity of the tumour and by its involving and being very adherent to all the adjacent structures, and not merely appearing as a simple hypertrophy of the gland. Microscopically, the fibrous tissue seen is what would occur in a case of simple enlarged prostate, but the infiltrating cells, though in definite outline, seemed mostly to tend to a small round type. Whether the growth was scirrhous, encephaloid carcinoma, or sarcoma remains doubtful.

Havelock road, Hastings.

NEPHRITIS OF OBSCURE ORIGIN IN SEVERAL CHILDREN OF ONE FAMILY

By A. H. BENSON, L.R.C.P. LOND. &c.

A CHILD aged twelve months was first seen on April 6th, 1889. There was general anasarca. His parents had not noticed that he was ailing till the same morning. The urine, which was of high specific gravity, was almost solid with albumen. The dropsy somewhat decreased under treatment, but convulsions set in which terminated fatally on May 1st. On April 26th, 1890 another child, aged four years, was noticed to be unwell and the urine was tested, again albumen in considerable quantity was detected. No further symptoms developed till the middle of 1891, when dropsy of the scrotum and legs set in. This disappeared under treatment and he remained well to all outward appearance, though there was still a large amount of albumen. In the spring of 1892 the quantity of albumen increased. Sick ness and convulsions came on, which proved fatal on May 1st. At the necropsy all the organs were found to be healthy except the kidneys, which were pale and somewhat enlarged. Whilst he was ill, yet another child (born a day or two after the death of the first patient) was found to have a trace of albumen in his urine, which rapidly increased. He also became dropsical and died in convulsions about a year after the albumen was first noticed. And now, to finish the series of cases, the baby, aged thirteen months, is in the same condition. The urine is scanty, of high specific gravity and simply loaded with albumen. There is no trace of blood or casts. At present there is no dropsy. The parents are first cousins. The mother had post-scarlatinal nephritis when a girl, but recovered completely. There is no other case of kidney trouble on either side. The two eldest children are healthy. There is no history of scarlet fever or diphtheria, nor has there been any in the village, to my knowledge, within the last five years. The house, well built and drained, lies rather low down in a somewhat marshy district, where I believe ague was prevalent

some twenty years ago. The treatment has included rest in bed, milk diet, vapour baths, free purgation with the various diaphoretics and diuretics, perchloride of iron in full doses, fuchsin, apocynum, diuretin and chloral hydrate. I have had the assistance of Drs. Frederick Roberts Rossiter, Singleton Smith, and Messrs. Chadwick and Collins. I should be extremely grateful for any help as to treatment for the remaining case, also for any explanations of four children in the same family being affected in the same manner without any apparent reason.

HOSPITAL PRACTICE, BRITISH AND FOREIGN

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium

ST BARTHOLOMEW'S HOSPITAL

INTESTINAL OBSTRUCTION PRODUCED BY A BAND,
ABSENCE OF MARKED SYMPTOMS FOR FIVE DAYS,
LAPAROTOMY, RECOVERY

(Under the care of Mr. HOWARD MABSH.)

THIS case is interesting as an example of intestinal obstruction due to a band, in which the symptoms were somewhat modified in character. There was apparently no history of previous abdominal attack, although the constricting band was regarded as probably of inflammatory origin, a history met with in more than half the cases. In other cases the band may be formed by the attachment of the free border of the mesentery, by Meckel's diverticulum or by the abnormal attachment of a normal structure (such as the vermiform appendix), whilst a similar result is effected by the passage of a loop of bowel through a hole in the mesentery or omentum. The usual course of these cases is very acute, with collapse, thirst and diminished urine. In 60 per cent the vomiting becomes stercoraceous by the forty-fifth day, and the patient quickly sinks unless relieved by operation.

A Blue-coat boy aged fourteen was admitted into the infirmary of Christ's Hospital, under the care of Dr. Alder Smith, on Oct. 24th last, with the history that on the previous day he had been attacked with sickness after eating unripe pears. An aperient was given, but the bowels did not act and he was sick several times during the day. Abdominal pain was slight and there was no distension, nothing abnormal could be felt, the temperature was normal. On the 25th sickness occurred twice or three times during the day and the bowels did not act, an oil injection was given but it was not retained, the boy felt very little pain. On the following day he was still sick. Small doses of opium and an injection, which, however, brought away no fecal material were ordered, he took only a little milk and a small quantity of beef essence. On the 27th nothing could be made out by examination of the abdomen, the temperature was normal there was no pain, very little distension and no sickness. By the 29th there was no further sickness, distension or pain, but the bowels had not been opened. Later in the day fecal vomiting suddenly commenced, but the boy's condition remained good, and he complained of only slight pain. At 8 P.M. Mr. Marsh saw him for Sir W. Savory, with Dr. Andrew and Dr. Alder Smith. The abdomen was only slightly distended, but coils of intestine could be seen through the abdominal wall. As the bowels had not acted since the commencement of the illness six days before, as fecal vomiting was present and coils could be seen, it was decided to perform laparotomy. When the abdominal cavity was opened by an incision below the umbilicus distended coils of small intestine presented. Two fingers passed through the wound detected nothing abnormal in the right iliac fossa or elsewhere. Two or three ounces of blood stained serum escaped. Search was now made for the obstruction, starting

CLINICAL SOCIETY OF LONDON

Prognosis of Sacro-iliac Disease—Removal of Malignant Growth of Colon through Inguinal Colotomy Incision—Lympho-sarcoma of Tonsil removed by External Incision

AN ordinary meeting of this Society was held on March 10th, Sir Dyce Duckworth, President, in the chair

Mr MAKINS read notes on the Prognosis of Sacro-iliac Disease, with three illustrative cases. One in an adult was treated by trephining and two in children were treated by arthrotomy with erosion. All three cases were or had been attended with suppuration. Some statistics were given regarding the rarity of the disease, the percentage of occurrence in childhood and the influence of sex. It was urged that the prognosis in tuberculous disease was better than the textbooks generally laid down, being materially influenced however, by the age of the patient and the position of the abscess and also that the disease should be treated on the same lines as tuberculous affections of the other joints.—The PRESIDENT remarked that Mr Syme used to employ the actual cautery in cases of this kind, and he remembered that the results were excellent.—Mr HULKE submitted that the record of two cases in children scarcely warranted any general conclusions being drawn as to the prognosis of this affection. The case which recovered seemed to be one of necrosis in which sequestra were removed, whilst in the other patient a sinus still remained. It was important to draw a distinction between those in which the disease was primary of the sacro-iliac articulation and those secondary cases in which the disease had extended from other centres. Statistics he only regarded as of value when they were from the practice of one person who furnished details of the evidence on which the diagnosis was based.—Mr GOULD said that the general opinion had been that the prognosis in these cases was exceedingly grave, this opinion might perhaps, be reconsidered in the light of the cases Mr Makins had related. Personally he had dealt with three cases. The first was that of a young woman aged twenty four with disease of the right sacro-iliac joint. There was a small abscess which he twice tapped and washed out with mercury solution, injecting iodoform emulsion afterwards. These measures failing he thoroughly scraped out the cavity and perfect recovery ensued. The second case was that of a man aged sixty who had two large abscesses in the buttock, the upper communicating with the sacro-iliac joint. A sinus in this case persisted after scraping but the patient had a tuberculous family history. The third case was that of a young woman under thirty years of age with an abscess connected with the left sacro-iliac joint. He opened it and removed all the bare bone he could, but a fatal result ensued, and it was then found that a large part of the sacrum and ilium was involved in the carious process, the tuberculous disease being locally infective, was apt to spread very widely in cancellous bones.—Mr MAKINS, in reply, said that his object was to show that the prognosis in children was a little less unfavourable than had been stated. Where there was extensive disease of bone the cases fell into the same category as those of similar lesions of the hip-joint.

Mr HERBERT ALLINGHAM related a case of Intestinal Obstruction of six weeks duration, in which inguinal colotomy was performed and a malignant growth was removed from the inguinal incision. There had been obstruction of the bowel for about three months, for the last five weeks it had been complete. The abdomen was greatly distended and no growth could be felt in the rectum. An incision was made as for left inguinal colotomy. On introducing the hand into the abdomen the obstruction was found to be due to a malignant stricture of the sigmoid flexure. The growth, with about fifteen inches of the gut, was pulled through the inguinal incision and fixed outside the abdomen. The gut was then incised on what was presumed to be the proximal side of the growth, but no faeces escaped. Attention was then turned to what appeared to be gut on the distal side of the growth. On incising this a quantity of faeces and flatus escaped. It was then evident that the gut was twisted. A Paul's tube was inserted and so faeces prevented from running over the wound. Ten days later a spiked clamp was applied to the protruding gut and the cancerous mass removed weighing fourteen ounces and a half. The clamp was left on for thirty six hours and then removed when there was not the slightest bleeding. In about fourteen days all was healed. There was no prolapse and the bowels acted from the lower of

the two orifices in the groin, showing that the gut was twisted when forced into the inguinal wound.—Mr BARKER inquired if the proximal coil of gut was much distended.—Dr GLOVER asked if the obstruction was absolute and complete.—Mr GOULD said that rotation of the sigmoid had been before discussed and that the proximal coil had been closed by mistake and dropped back into the abdomen. He wondered if it would not have been better to have relieved the obstruction and then later removed the growth, restored the continuity of the gut and dropped it back into the peritoneum. He asked if the glands in the meso-colon were involved.—Mr HULKE asked if the condition of the coats of the intestine was such as to allow of suture.—Mr BUCKSTON BROWNE referred to the case published in THE LANCET of March 11th by Mr Treves and commented on its analogy with the case under discussion.—Mr MAKINS said that he knew of another case in which, after removal of the growth, the intestine had been sutured and dropped back into the peritoneum.—Mr ALLINGHAM, in reply said that, when the intestine, with the growth, was pulled through the small opening in the abdominal wall, this emptied the gut and made both the proximal and distal portions appear of about equal size. The obstruction was practically complete, only a little flatus and fluid being passed. It was undesirable to drop back the distal portion of the gut, not only because it might be mistaken for the proximal end, but because accumulated faeces in it might set up ulceration, and it was often desirable to wash through from this opening to the rectum. The wall of the intestine was very thin, so that suturing would have been difficult, and the patient's condition was too unfavourable to allow either of examination for enlarged glands or for suture and return of the intestine after the removal of the growth.

Mr RAYMOND JOHNSON read the notes of a case of Lympho-sarcoma of the Tonsil removed by external incision with preliminary ligature of the external carotid artery. The patient was a woman aged fifty three, whose symptoms were of about six months duration. The growth, which occupied the position of the left tonsil, was oval in shape and measured one inch and a half by seven eighths of an inch in its two diameters, its surface was covered with short papillary processes. A mass of soft glands was situated below and behind the angle of the jaw and other smaller glands lay along the posterior border of the sterno-mastoid. Notwithstanding the somewhat extensive nature of the glandular infection it was decided to operate. This was done on June 20th, 1892. The incision extended from the lobule of the ear to the level of the hyoid bone and from it an incision was carried to the extent of one inch along the anterior border of the sterno-mastoid. The mass of glands was easily dissected out and then a silk ligature was applied to the external carotid artery below the origin of the lingual. The lateral wall of the pharynx was next freely exposed and the primary growth was excised, together with a margin of healthy tissue around it, by means of scissors. The hemorrhage was very trivial. The skin incision was sutured with silk and drained at the lower angle, no attempt being made to close the opening in the wall of the pharynx. Rectal feeding was adopted for two days after the operation. The patient progressed without a bad symptom except some suppuration in the lower part of the wound. On July 14th the enlarged glands behind the sterno-mastoid were excised through an incision along the posterior border of the muscle. The patient was discharged on July 23rd. In December a small gland was excised from beneath the scar behind the jaw and other very small ones were felt in both sides of the neck. The patient's general health had much improved and there was no recurrence in the pharynx. Reference was made to the other modes of removing tumours of the tonsil. The incision made was very similar to the one made by Cheever and Golding Bird. It was urged that the application of a ligature to the external carotid artery, which added very little to the difficulty or length of the operation was a more satisfactory mode of dealing with hemorrhage than such methods as the performance of a preliminary tracheotomy or the removal of the growth with the cautery. The patient who was exhibited eight months after the operation was in good general health and free from recurrence in the month, but there were some slightly enlarged glands in both sides of the neck.—Mr H. ALLINGHAM spoke of the ease with which the growth was reached and removed through the external incision.—Mr BARKER said that he had operated on three cases and confessed himself still in favour of removal through the mouth. The prognosis in these cases was

spongy On a careful exploration of the prostatic portion of the urethra with the finger a polypus the size of a haricot bean was found attached to the floor of the urethra with its body projecting forward, and in the upper surface of the urethra was a depression which corresponded with the body of the growth. The polypus was removed by a pair of scissors, and the patient sent to bed with a drainage tube in the bladder. After a somewhat tedious convalescence recovery ensued, and now, a year and a half after the operation, the patient was well, and his prostate had contracted up to its normal size. The growth proved by microscopical investigation to be purely prostatic. Mr Bryant made some comments on the case, which seemed to him to be very unusual. Indeed, he was unable to point to one like it. He drew the attention of the Society to the fact that the growth would never have been discovered if the fashionable supra pubic operation had been performed. Mr REGINALD HARRISON said that the history of the case showed the importance of adopting the perineal procedure in all cases of growth or of bleeding—at all events, within the region of the prostatic urethra. When the growth or other source of the bleeding was within the bladder the question of supra pubic operation might be open to be considered, but the mortality on this latter operation was far greater than with the perineal operation, and this, he believed, was due to the fact that it was resorted to in cases in which it was not applicable. Mr HULKE remarked on the analogy between the causation of hæmorrhage in this case and that occasionally observed in connexion with the presence of a polypus springing from the canal of the uterine cavity. Mr WARRINGTON HAWARD mentioned that he had recently removed a polypus from the bladder which corresponded very closely in shape and appearance to that shown by Mr Bryant. The man from whom it was removed had suffered from very profuse hæmaturia for six months previously. Failing to find a stone, he explored the bladder through the perineum and alighted upon a little polypus, which he twisted off without difficulty, removing an adjacent papillomatous elevation with the finger nail. From that time the hæmorrhage ceased. Mr CROFT, referring to the question of diagnosis, said that the only symptom which suggested that the tumour was not in the bladder, but in the prostatic urethra, was that blood flowed from the penis independently of the act of micturition. Mr CAMPBELL WILLIAMS suggested that if the urethra had been examined with the endoscope the growth might have been found, and he related a case in which by this means he discovered and removed a small polypus beside the veru montanum which had given rise to a troublesome urethral discharge. Endoscopic examination was particularly easy in young people with chronic gleet. The granular patches in the prostatic urethra were readily seen, local treatment soon diminished the size of the prostate, and the troublesome frequency of micturition ceased. Mr BRYANT, in reply, said it was probably generally accepted at present that in all cases of hæmorrhage the source of which was obscure the perineal exploratory incision was a perfectly justifiable operation. Mr Hulke's analogy would only apply to the case of a polypus from the cavity of the bladder that had been extruded into its neck, just as in Mr Haward's case. The occurrence of hæmorrhage independently of micturition was certainly an important diagnostic feature, for it showed conclusively that the source of the blood was anterior to the neck of the bladder. The curious point in the case was the fact of its being a myoma, showing that it came from the prostate. He was astonished to find how promptly the prostate returned to its normal calibre.

Dr DONALD W HOOD read a communication on the Etiology of Rötheln. He briefly referred to the clinical symptoms, which were generally known as rötheln, rubeola, or German measles. He drew attention to the extreme diversity of opinion held by various writers on the etiology of this affection, and he pointed out that these opinions differed not only as to the essential nature, specific or otherwise, of the contagion, but as to what might be looked upon as the fundamental symptoms of the disease. He endeavoured to prove on clinical as well as theoretical grounds that a hypothesis was not untenable which assumed that the specific contagion of measles being a living organism, as such would be liable to undergo variation and would be subject to evolutionary changes in adapting itself to varying conditions of "soil," and that some such hypothesis would afford a clue towards explaining the many affections of exanthematous character which departed more or less from the

true measles type. Clinically many conditions were known as rötheln. These conditions differing widely in both intensity and symptomatology, the writer would ask, Were such affections due to the same contagion, assuming different degrees of force or intensity, and profoundly modified by different states of "soil" and environment, or were they due to contagia specifically distinct the one from the other? In support of the hypothesis attention was directed to many points in the clinical history of measles and so-called rötheln. These points were severally discussed under the following heads. Personal experience of the various forms of exanthemata differing materially from ordinary measles, the variation in symptoms found with measles, immunity did it depend upon intensity? would a mild attack of measles confer immunity in the same degree as did a severe one? second attack of measles, the modification of measles by environment and by difference of "soil," the mutual want of protectiveness between rötheln and measles might it possibly depend upon degrees of intensity? was the general type of measles less severe than formerly? special reasons why the contagion of measles was placed under conditions which would apparently favour variation.—The PRESIDENT observed that much of the confusion and difference of opinion that had arisen amongst those who had described these measly rashes was due to grave errors of diagnosis. No diagnosis should be arrived at on the strength of any one symptom, but on that of the whole natural history of the case concentrated into one conception.—Dr ROUTH said his experience was that whenever any particular disease was present in the form of an epidemic other diseases were met with closely resembling it, but which were not it. The crucial test would be whether by inoculation of one disease one could produce the other disease. He looked upon the two affections as perfectly distinct. He pointed out that in rötheln the eruption did not, as in true measles, commence on the face, there was no cough or eye affection as in measles. The character of the eruption was very marked, being more blue in tint and partaking more of the roseolar element. Moreover, the lymphatic glands were uniformly enlarged in rötheln and not in measles, and directly the rash began to disappear all the symptoms disappeared also with remarkable rapidity.—Sir DYCE DUCKWORTH held that the two diseases were easily distinguishable, though cases occurred in which one seemed to merge into the other, this, however, had been observed in respect of many other of the exanthemata. He pointed out the differences in the period of incubation and the characters of the eruption between morbilli and rötheln, and referred to other clinical peculiarities in the latter, such as the sudden rise of temperature for a time, the affection of the throat and the general enlargement of the lymphatic glands. The protection which had for generations been afforded to infants by vaccination did not appear to have been transmitted to subsequent generations in respect of small pox and he therefore saw no reason to suppose that any immunity against measles should develop. The diminution in the incidence of measles was rather to be found in variations in intensity of the poison.—Dr PYE SMITH, speaking from experience, had not found it so very difficult to distinguish one disease from the other. After pointing out the differences in the symptoms of the two affections, he said that the distinction ought not to depend merely on the similarity or otherwise of the symptoms, but one ought to consider the natural history of the two diseases as a whole. There was at present no knowledge of the existence of a microbe in either of these diseases, and therefore it was premature to apply the logical doctrines affecting microbial development, and, further, there was no evidence that would justify the assumption of any transformation in pathogenic microbes. The alleged change of type of measles was probably due to conditions similar to those present in the Fiji epidemic.—Dr ENDOWES mentioned the case of a family which, shortly after suffering from an affection the symptoms of which accurately corresponded to German measles, was attacked by true measles. He thought that rötheln might be fully described as a disease that began like measles and later assumed the appearances of scarlet fever. He was inclined to believe that there was no set period of incubation for any disease, but that it depended more upon the condition of soil and the dose of the poison than on the nature of the disease.—Dr HOOD, in reply, said that he had only attempted to furnish a plausible explanation of the diversity of opinion that prevailed as to the relationship of these two diseases.

some years ago. The abdomen was full of fluid of glutinous character, and both ovaries presented thin walled and vascular cysts, which were ruptured at their ends, the latter being opened out like the petals of a flower.—Dr CULLINGWORTH remarked that both cases were typical of the difficulties in diagnosis which were present in many cases of abdominal tumour.—Dr SOLOMON SMITH asked if the intestines ultimately returned to their proper position.—Mr BATTLE, in reply, remarked on the serious nature of the cardiac complication in the second case. There was nothing to indicate the method of rupture of the cyst. He believed that the intestines returned to the lower part of the abdomen after the operation.

PATHOLOGICAL SOCIETY OF LONDON

Survey of Recent Work bearing on the Pathology of Cancer and Sarcoma

(Continued from p. 561.)

DR. ARMAND RUFFER, in continuing the debate on the above subject, said that he spoke in the names of his collaborators, Messrs. Walker and Plimmer, as well as for himself. He objected altogether to the word "psorosperms" which Mr Jackson Clarke had used. The psorosperms were a class only of the protozoa, and therefore Mr Clarke's contention that he used the word "psorospermiosis" on account of its indefiniteness was illogical. Until the whole of the life-history of these parasites had been worked out it was much better to use the word "protozoa." Thanks to the courtesy of Mr Clarke, he (Dr Ruffer) had had the opportunity of examining some of his preparations and he had no hesitation in saying that in his opinion there was not a single structure in any of them which could possibly be mistaken for a parasite, and that all he saw were cellular elements, some normal and others degenerated. He might refer to some preparations shown by Mr Clarke at the Society's meeting on Feb. 21st. The first two were described as (1) "cystic breast, logwood-eosin staining showing plasmodia," and (2) "sarcoma of femur, degenerated parts showing psorosperms and plasmodia sporing, Biondi's staining." The first section evidently consisted of fibrous tissue, there were a few round bodies, which stained very darkly with logwood and showed an intra nuclear network. He had no hesitation in asserting that these bodies, called plasmodia by Mr Clarke, were simply tissue nuclei, as they had all their characteristics, were undistinguishable from nuclei and were, in fact, perfectly healthy typical nuclei. The second preparation showed a large body of irregular shape, in which nuclei could still, though indistinctly, be seen, around it granular detritus and a few brown bodies could be distinguished. He did not know on what evidence Mr Clarke based the supposition that certain of these structures were plasmodia sporing and that others were psorosperms, but he had not the slightest doubt that the large body was the ordinary giant-cell found in myeloid sarcoma and that the surrounding bodies were red blood-corpuscles. They were sharply outlined, concavo-convex, and presented all the appearances of red blood-corpuscles insufficiently stained with Biondi's reagent. Another section was labeled "carcinoma in septum of the nose, stained red," the section was not sufficiently stained or properly cleared, so that all that could be seen were a few round bodies, which stained faintly with carmalum. It was impossible to say from the preparation what these bodies were, and had the section been labeled "section of testis," or "spleen," or "lymphatic gland," or even of "vegetable tissue," no one could have contradicted it, for it was impossible to make a diagnosis by looking at the preparation. Mr Clarke had also shown him a section of carcinoma of septum of the nose in which he described a large plasmodium with a nucleus sporing. In his opinion this large plasmodium was nothing more than a typical epithelium cell, and he was ready to demonstrate that kind of plasmodium in any section of skin from any normal, healthy person. If Mr Clarke chose to call epithelial cells plasmodia, then all he (the speaker) could say was that the healthy body, from the crown of the head to the tips of the toes was lined with large plasmodia provided with sporing nuclei, and that there was no reason why the liver, for instance, should not be described as a large bag lined with psorosperms. Lastly, he would draw special attention to the fact that not in a single preparation which Mr Jackson Clarke had shown did there appear to be demonstrated a

single parasitic body such as Soudakewitch, Foa and himself had described. He considered the whole of Mr Clarke's theories to be based on a succession of pathological mistakes. He (Dr Ruffer) then referred to his own work on the subject, entering more specially into a discussion of the objections raised by his friend Professor Boyce, as to the possibility of these parasitic bodies being simply chromatin corpuscles which had found their way out of the nucleus. In his opinion this was impossible, since these parasitic bodies did not show the reaction of chromatin, after having been treated with Foa's solution, with picric acid, or with chromic acid and alcohol and stained with aniline blue and eosin. The two substances, that formed the nuclei of the parasite, and the chromatin forming the cell nucleus, were absolutely different in all their micro chemical reactions. On the other hand he thought he could confirm the observations of Messrs Shattock and Ballance as to the extrusion of small chromatin particles out of the nucleus, and as to their finding their way out of the cell, but he was unable to attach any signification to this phenomenon, as a similar appearance could be seen in normal epithelial tissues. The fact that it occurred in animals during foetal life was proof positive that these small chromatin particles were not parasitic in their nature. Dr Ruffer then gave a description of the mode of reproduction of parasitic bodies which he had observed in carcinoma. The reproduction was carried out through the division and subdivision of the parasite's nucleus, the capsule then also subdivided, until at last a whole zoogloea-like mass of parasites was produced. The formation of true spores he had never observed, but it was quite possible that these young parasites were more resistant, and possessed some of the functions and properties of true spores. Lastly, he would again repeat that it was evident to him, to Mr Plimmer, and to Dr Woodhead that Mr Jackson Clarke did not appreciate the specific character of the parasite which he (Dr Ruffer) had described, as he was quite unable to demonstrate it in a single one of his preparations. He had spoken strongly because he thought that sweeping statements as to the cause of cancer and sarcoma, such as Mr Clarke had made, did incalculable mischief, not only amongst the medical profession, but even among the general public, and he considered it therefore only right that one who did not claim to be an authority, but who had, nevertheless, arduously and conscientiously worked at the subject with the best available methods, should come forward and say that the conclusions were erroneous because the supposed facts on which these conclusions were based could not be demonstrated. Dr Ruffer concluded by saying "He had no wish to do anyone an injustice, he proposed, therefore, that Mr Clarke's sections be referred to a special committee, and if they found that his interpretation was wrong or that he had done Mr Clarke an injustice, he would come forward and acknowledge his mistake publicly."

MR JACKSON CLARKE, in reply, said that he used the term "psorosperm" in the same sense as Cobbold, Malassez, Silcock, Delpine and others. If the name of any other person were to be associated with the parasites it should certainly be that of Pfeiffer, who first published an account of them. It was most undesirable to attach the name of any observer to any single stage of the parasite's existence, because if this were done there would soon be quite a directory of names in use. He was surprised that none had criticised his paper on psorospermiosis of the urinary tract, because with that his work on cancer and sarcoma stood or fell. Dr Boyce had given an exposition of the views of cancer universally accepted three years ago, but now no longer tenable. He had not explained the fact that the large, apparently degenerated cells met with in squamous epithelioma could be anything but sporozoa, which he (Mr Clarke) held was proved by the sections he placed before the Society. If Dr Woodhead was right in his interpretation of the appearances demonstrated by himself, then it followed that he had made many new observations, such as the presence in sarcoma of intra cellular cells some of which had exactly the characters of those described by Soudakewitch in cancer and others exactly corresponding to those described by many observers in cancer as sporozoa in their various stages of life. The opinion of Mr Laurie, an experienced biologist, agreed with his own that the specimens from the milk-ducts showed cocoidal infection. He had no doubt that the Ehrlich Biondi stain had led Ruffer, Walker and Metchnikoff to mistake swarm spores for phagocytes. He rejected the hypothesis of cell invagination. The normal epithelial cells were developed under pressure, but they were not invaginated, though some

grave and life was, as a rule, only prolonged for a time, if the same relief could be got from a milder operation the latter should be chosen. He had vertically divided the mucous membrane over the tumour with a Paquelin's cautery and then shelled out the growth with the finger and a blunt instrument, taking the precaution to first remove the glands in the neck, leaving a sponge in the wound, so that he could easily press on the vessels if hemorrhage in the mouth should be troublesome. Of his three cases one (a male) was alive a year after operation, and of the remaining two (females) one died eight months after wards of recurrence, whilst the other (a young woman aged twenty three) was alive three or four years afterwards. — Mr JOHNSON, in reply, said that the tumour he removed was unlike the encapsuled ones which had been referred to, but was of such a nature that it could not have been shelled out unless the whole mucous membrane round it had been divided by cautery.

MEDICAL SOCIETY OF LONDON

Treatment of Lupus of Face by Free Removal and Skin Grafting with Large Flaps — Abdominal Section for Tumours presenting unusual Characters

AN ordinary meeting of this Society was held on March 13th, the new President, Dr Bristowe, taking the chair for the first time. Unanimous votes of thanks were accorded to Mr Hutchinson, the retiring President, and the other retiring officers of the Society.

Mr BRUCE CLARKE read a paper on the Treatment of Lupus of the Face by Free Removal and Skin Grafting with Large Flaps. After alluding to the length of time which had elapsed since skin grafting had first been attempted, he passed briefly in review the various plans which had been adopted for the repair of lost skin, pointed out how great an improvement had been effected by Wolfe's method and finally by Thiersch's, which was the mode referred to in his paper. He briefly described the mode of cutting the grafts and pointed out that it was necessary to arrest all bleeding before applying them to fresh surfaces, otherwise they would not adhere. He had treated some six or seven cases of lupus by this plan, and was certain that it was a great improvement on mere scraping. He had made a series of microscopic sections of one case on which he was operating and he felt sure that much more tissue must be removed than could easily be done with a Volkmann's spoon if the diseased structures were to be extirpated, and unless this were done no permanent cure would result. — Mr Bruce Clarke then showed two cases the first was that of a young woman on whom he had operated about eleven months ago, removing the lupoid tissue by excision, baring the cartilage of the nose and clearing out the diseased mucous membrane from the interior of the nasal cavity. The second case was also in a woman, and was one of lupus of the nose of a more exuberant character. In this, owing to failure to excise the growth at the margin, there had been a slight recurrence of the disease. — Mr WATSON CHEYNE also showed a case of lupus of the face in which both cheeks were extensively involved. He excised the growth freely, including the skin, for from a quarter to half an inch beyond the patches and then applied very extensive grafts. The back of the hand, which was also involved, was treated in the same way. — Mr L. BIDWELL exhibited a girl aged nineteen, who had a large patch of lupus on the inner side of the thigh, which had been freely excised and the raw surface covered with Thiersch's grafts. A good result had been obtained. He showed another woman with an extensive patch of lupus over the front of the shoulder. Scraping and treatment by Unna's plaster having failed, he freely dissected out the diseased tissues, removing the subcutaneous fat at the same time, with a good result. — The PRESIDENT thought that the measures recently introduced tended greatly to minimise the danger of recurrence of the disease. — Dr RADCLIFFE CROCKER said that the method at present in vogue was as great an advance upon scraping as scraping had been upon previous methods. For the last two years whenever he had dealt with a small patch he had practised excision. In order to prevent the graft curling up it should be laid on a sponge and then applied to the raw surface in the same way that a gilder used gold leaf. — Mr BALMANSO SQUIRE referred to a case which Mr Durham showed some years ago at the Clinical Society in which after excision of a patch of lupus, he partially detached small

strips of skin from the periphery and moved them towards the centre of the raw patch. The method under discussion could not be applied to lupus of mucous membranes. For lupus of the ala of the nose he held that the best treatment was scraping with a very small sharp spoon and following this by linear scarification. — Mr C. B. LOCKWOOD said that the results which had been obtained were better than those usually seen after treatment by ordinary methods. The tissues far beyond the seat of the growth, whilst looking apparently healthy, would often be found on microscopical examination to show the cell infiltration characteristic of the disease. — Dr SOLOMON SMITH said that the sheet grafting left a cicatrix which possessed great elasticity. If it were necessary after the operation to plug the nose with iodoform gauze the latter should be wrapped round a drainage-tube to permit of air passing through, which prevented an ozonic odour developing. — Mr BRUCE CLARKE, in reply, said that the recurrence in one of the cases was due to the fact that he had not removed the skin surrounding the ulcer sufficiently freely. By injecting tuberculin beforehand a surgeon might be able to better define the limits of the outlying patches.

Mr W. H. BATTLE related two cases of Abdominal Tumour which presented features of unusual interest. Both were probably of ovarian origin and were unusually movable, but differed altogether in their composition, in their history and in the symptoms to which they gave rise. The first case was that of a married woman aged forty-one, who applied at the out patients' department of St. Thomas's Hospital in July of last year. She presented a lipoma of the shoulder of eight years' standing and a tumour of the abdomen, which was first noticed nine months previously. The tumour was round, smooth, of the size of an orange, flattened and painless, it lay usually in the right iliac fossa, but could be carried into either lumbar region, upwards under the liver or even into the left hypochondrium, always returning to its original position. The tumour was cut down upon by a median incision, it was found to be fluctuating and was therefore punctured, but no fluid came through the instrument. The contents, which consisted of hair and fat, were therefore evacuated by pressure, and the tumour drawn through the incision and separated from its attachments. These were three in number to the omentum by means of a thick, broad band, to the right ovary, which was small, by a thin pedicle, and to the large intestine by a long adhesion. The patient made an uneventful convalescence. Mr Battle insisted on the difficulty in arriving at an accurate diagnosis, opinions varying between movable kidney, floating spleen, subperitoneal pedunculated fibroid, ovarian tumour with a long pedicle, lipoma of omentum and dermoid cyst of omentum. He alluded to a somewhat similar case under the President's care which was removed by Mr Sidney Jones from a woman aged thirty-five. The second case was that of an unmarried woman aged twenty-one, admitted to St. Thomas's Hospital on June 28th, last year, with an abdominal swelling. There was a history of empyema discharging externally eleven years previously. Three months before admission the abdomen had begun to swell, with increased shortness of breath, but no palpitation, there had been hematemesis and cardiac valve lesions were present. The abdomen was much distended, but there were no enlarged veins, a cross thrill could be easily obtained. There was a large fluctuating hernial swelling in each labium, easy of reduction, and a protrusion of the posterior vaginal wall. There was transient albuminuria. Later a large hard mass was felt in the abdomen a little to the right of the middle line, freely movable in every direction. A median incision was made into the abdomen and ten pints of thick glutinous fluid evacuated from the peritoneum. A multilocular cystic tumour was found originating in the left ovary the cysts containing very thick fluid. It had a very long pedicle and one of the loculi was found to open freely into the peritoneal cavity. In consequence of the prolonged pressure of the heavy fluid, the small intestines and omentum after the operation remained in the upper part of the abdomen, and showed no tendency to fill the lower part of the pelvis leaving consequently a large unoccupied space, across which the abdominal wall passed something like the membrane of a drum. A quantity of air was found to occupy the hernial sacs for nearly three weeks after the operation. Owing to the signs he was at first inclined to regard the case as one of sarcoma with secondary peritoneal growths and nodules. — The PRESIDENT quoted a case in which he made the necropsy

quality of its practitioners of verse who were or are practitioners of the healing art. Not to mention Keats, cut off in the preliminary stage of the medical career, there are Thomas Lovell Beddoes, memorable if only for his simile of the violet—

"Like Pandora's eye
When first it darkened with immortal life,"

David Macbeth Moir, some of whose lyrics and sonnets can perish only with the English language, Edward Gordon Rake, Oliver Wendell Holmes (American by birth, but English by mother tongue), and S. Weir Mitchell, also a Transatlantic physician of approved poetic power. North of the Tweed we have in more than one contributor to the "Lays of the Colleges" a striking exemplar of Carlyle's medical "singer"—notably the late Dr. James A. Sidey, whose "Burnie that runs to the Sea" may rank with the best lyric of Tannahill or the Ettrick Shepherd, and the editor of that volume himself, Sir Douglas MacLagan, whose translations from the German are hardly inferior to their masterly originals. Nor even in our own day are there wanting rivals of the Latin medical poets so numerous in the sixteenth century. Sir Henry Hallford, whose biography we are glad to see announced, was the author of beautiful elegiacs and the late Dr. Francis Adams of Banbury, N.B., also published specimens of the Ovidian or Propertian muse not unworthy of the *genus loci*.

Mr. John A. Goodchild has been for some time before the world as a medical poet, and his "Somnia Medici," of which the three instalments are now in their second edition, disclose rare powers of imagination and rhythmical expression. His mood is a versatile one and ranges from the simple ballad to the elaborate sonnet, from the occasional lyric to the dramatic dialogue, from the airy satire to the delicately coloured idyll. He makes no attempt to produce a great whole, probably the conditions under which he writes are not favourable to anything like prolonged or sustained effort. But all he gives us is carefully finished, the evident product of a fastidious workman, schooled under many masters and inured to severe self-criticism. The reader soon responds to a poet who withholds all but his best, and he finds his reward in compositions which are never without original thought or refined sentiment, conveyed in verse almost uniformly felicitous in choice of metre and harmony of cadence. Open any volume of the three at random—the earliest, for instance—and the reader will not go far without finding our criticism justified. In "The Withered Rose" (First Series, p. 8) he will recognise a romance "most musical, most melancholy" unfolded in rhymed triplets that break on the ear like the measured plash of the sea wave on the shore, rising and falling from time to time in a noble "trikumla," as the Greek critic would have said. The idea thus rendered is the old, old one of earthly love bereft of its object, whilst its sense of privation is softened with the hope that the "solution of continuity" is not eternal, but that reunion will be effected in a not distant hereafter. Mr. Goodchild has given a freshness all his own to the theme and embodied it in verse which haunts the sympathetic reader. There is merit of an equal, though diverse, kind in "Winne," in "In a Studio," and in "Honour" the latter full of powerfully dramatic touches. From these studies in character and situation the transition to the passing controversies of the day is considerable, but here again Mr. Goodchild maintains his unusually high level of thought and expression. In "Anti vivisection" we have a pungently satirical sonnet directed at a notorious agitation, followed up by another composition of the kind approximately called "Antics," in allusion to the "anti" mood so dear to many whose first instinct is to "oppose," however undeserving of "opposition" the cause or the creed may be. All through his poems, indeed, Mr. Goodchild appears as the vindicator or apologist of the profession, whether directly in his exposure of popular fallacies or

narrow minded "fads," or indirectly in his continuous demonstration that the work-a-day life of the medical practitioner implies nothing of that divorce from culture and literature which supercilious outsiders are sometimes prone to assume. His volumes, of which the space at our command compels us to notice the first only, are one proof the more that literary, even poetic, accomplishment of a high order is not incompatible with a calling the practice of which leaves but too little time for its published manifestation, and that, if other professions have contributed more largely to the library of the man-of-letters or of the *dilettante* than the medical, it is for no lack of power in the latter, but rather from the time denied to it or from the opportunities withheld from it.

Physiologie Travaux du Laboratoire de M. CHARLES RICHEL, Professeur à la Faculté de Médecine de Paris. Tome I. Paris: F. Alcan, 1893.

THIS, the first volume representing the work done in M. Richet's laboratory, contains eighteen memoirs by himself or by his pupils, some of which date back as far as 1880 and are only reprints. Though most of them have been published elsewhere, M. Richet thinks that, as they deal with facts and not with theories, they may prove of service to the working physiologist, especially as they have appeared in different journals now not easily accessible. He promises two more volumes in the course of the ensuing year, of which the first will contain the memoirs by students working in his laboratory on chemical physiology and the second their studies on toxicology and pathological physiology. The section on Animal Heat contains a very exact and interesting account of the history of calorimetry, from the first experiments of Lavoisier to the present time. In the course of this the author observes, in a note on Dr. Wood's experiments made in Philadelphia, that the use of English weights and measures instead of the decimal notation practically dooms a scientific work to neglect on the continent, for few, like himself, will take the trouble to make the necessary calculations for their conversion. He describes Lavoisier's, Dulong's, Senator's, D'Arsonval's and his own ingenious instruments, and gives many details of the difficulties he encountered and of the sources of error he had to avoid. He points out the influence of size in the animal, of external temperature, of the integument, of the nervous system and of other conditions on the production of heat.

The republished memoirs of M. Charles Richet himself are—1. A Contribution to the Physiology of the Nervous Centres and Muscles of the Lobster, which contains much matter now incorporated into our text-books. 2. The Movements of the Frog following Electrical Excitation. 3. The Influence of the Duration and of the Intensity of Light on Luminous Perception. In this essay M. Ant. Breguet's name is associated with that of M. Richet as joint author of the paper. 4. Experiments on the Brain of Birds. 5. Psychical Blindness induced by Experiment in the Dog, with Necropsies. 6. On the Muscular Sensibility of Respiration, written in conjunction with M. P. Langlois. 7. On the Duration of Reflex Phenomena in Anæmia. 8. Two Experiments on Inhibition in the Frog. 9. Researches in Calorimetry. 10. On the Weight of Animals. 11. A New Function of the Medulla Oblongata—viz., the Regulation of the Temperature of the Body through the Respiration or Thermic Polypnoea. 12. On the Respiratory Exchanges in Man, written in conjunction with M. Hanriot. 13. On the Respiratory Exchanges of the Dog. 14. On the Respiratory Exchanges in Mammals. 15. On the Respiratory Exchanges in Birds. M. Langlois contributes a memoir on the Study of Calorimetry in Man, M. Rallièrre gives an account of his Experimental Researches on Death by Asphyxia, and M. Saint Hilaire writes on the Influence of Organic Temperature on the

of them were flattened. He had frequently observed that a cell infected by a parasite had been carried into another cell, and the parasites surrounded and indented each other. He had also frequently observed spores in these so called "invaginated cells." As to the hypothesis of central keratinisation put forward by Boeck and others to account for certain cell inclusions, it was in the highest degree improbable, because in normal conditions keratinisation was always peripheral, and though drops of keratin hyaline might appear centrally they dissolved again in the cell protoplasm before keratinisation occurred. These so called keratin masses were present in sarcoma as well as in cancer, and were ripe psorosperms. He regarded the phenomena observed by Messrs Shattock and Ballance in sections of incubated cancers as due to the life of the parasites continuing after that of the tissue had ceased. If the intra cellular stage of the parasite were the only one present in cancer, it might be dismissed from consideration, and seeing that the pathological features of cancer and sarcoma were so much alike, anything besides epithelial cells that happened to be present in cancer could be put aside as unimportant if similar bodies were not found in sarcoma. He showed sections and also photographs taken by Mr Roughton illustrating the process of spore formation in cancer and the intra cellular parasites in sarcoma. Some of the photographs from unstained, fresh specimens showed the details of structure quite as clearly as those taken from sections of cancer hardened and stained in various ways. He regarded all the "cells of endogenous origin" of Virchow and the "cells with irregular mitoses" of cancer and sarcoma of Klebs and others as parasites. He claimed to have fully demonstrated the process of swarm spore formation, and since the last meeting he had observed in cells from a duct of a cancerous breast the bodies placed before the Society with all the characters of lasting spores of the microsporidia. The parasites accounted fully for all the phenomena of cancer and sarcoma. Since the last meeting he had seen notices of a paper by Foa, who described in cancer coccidia which went through the process of swarm sporing the spores immediately attacking new epithelial cells. In another paper Wernicke had found sporozoa in mycosis fungoides, an affection everywhere regarded as a form of sarcoma. In conclusion, he confidently left his work to the proving of time.

The PRESIDENT (Sir George Humphry) remarked on the ability and the patience which had been displayed by Mr Clarke under the trying fire of adverse criticism. The subject was one of extreme difficulty, and even the most distinguished microscopists seemed unable to agree what were the changes due to protozoa and what were those due to vital changes in the cells themselves. The question still required much serious examination for its elucidation. And, furthermore, there remained the interesting pathological problem how far could protozoa cause the proliferation of cells and the development of intervening connective tissue which together made up the essence of cancer.

The following card specimens were shown —

Dr R. G. HENB. Specimens of the "Cancer Body"
Dr LEE DICKINSON. (1) Stenosis of Left Bronchus caused by Dilatation of Left Auricle, (2) Aortic Aneurysm bursting into Left Bronchus, (3) A simple Gastric Ulcer unusually situated.

Reviews and Notices of Books.

A Manual of Diseases of the Ear By GEORGE P. FIELD M.R.C.S. Fourth Edition London Baillière, Tindall and Cox 1893

THE issue of a fourth edition of this work is sufficient evidence of its popularity and of the growing interest taken in ear surgery. In this edition the work is considerably enlarged and a number of new illustrations have been added of an anatomical or pathological character. These have been undertaken by Mr Jackson Clarke and are, on the whole, clearly executed and accurate. The plan of exhibiting diseased appearances of the membrana tympani through a painted speculum has been adhered to. Some of these paintings, as that of muco-purulent collection in the cavity of the tympanum (p 198), seem to us too highly coloured and would give the idea to a novice that the membrane might

be a transparent structure. The illustration of multiple exostoses is excellent. It is well to point out, however, that these growths are very seldom situated as near the orifice of the meatus as here depicted. The illustrations of preparations on p 212 are exceedingly good. The chapter on exostosis is full and clear, and Mr Field still gives preference to the dental engine in dealing with ivory growths. An important addition to this work is the chapter on the results of suppurative middle ear mischief, in which a good summary is given of the leading symptoms of cerebral abscess and sinus pyæmia. Mr Field wisely does not divide and subdivide varieties of chronic middle-ear inflammation, and his directions for treatment are clear and explicit. In dealing with this subject he does not mention the operation of excision of the drum and ossicles so largely practised in America. In the chapter on tinnitus aurium he speaks of the proceeding, but appears never to have adopted it. Mr Field seems to take a more favourable view of tinnitus cases than do some aural surgeons, for he asserts that if suitable treatment be adopted cure is to be hoped for. The term "relief" would, we venture to think, better agree with the experience of those who have had much to do with these troublesome cases. As may be expected, Mr Field stoutly maintains the value of the pilocarpine treatment in labyrinthine deafness, and we are glad to see that in his book he agrees with Politzer that this drug is mainly useful in nerve deafness only. He throws out the hint that true labyrinthine deafness is, after all, exceptional, and that many cases that have been sent to him for this treatment were examples of other kinds of disease. Dr Cagney has written an excellent article on the electrical treatment of tinnitus and nerve deafness. From all points of view this work may be said to come well up to modern standards, while what may be termed experimental modern ear surgery is judiciously neglected. The book may be read and studied with advantage by anyone interested in the subject, and this improved edition will certainly maintain the popularity of its predecessors.

Somnia Medici By JOHN A. GOODCHILD First, Second and Third Series Second Edition London Kegan Paul, Trench, Trübner and Co 1892

CARLYLE, in a memorable passage, has told us how naturally the medical man may develop into "the singer" — given the true heart that determined him to the most humanitarian of all professions and the fine sense of the beautiful that belongs to every genuine student of the cosmos, moral and material. If to these essentials he adds what Wordsworth calls the "gift of verse," a gift often possessed by an unsuspecting owner and capable by culture of infinite improvement, he may almost insensibly become "the singer," such as every European nationality can show us and none in greater variety than our own. The sixteenth century of our literature produced distinguished medical poets, not a few of them Scottish, whose language, however, was mainly Latin, in which, as Arthur Johnston lets us see in his "*Delitæ Poetarum Scotorum*," the votary of Apollo may be as strong on his literary as on his therapeutic side. The century succeeding gives us others of not inferior merit masters "*utriusque lingue*," but most effective in the vernacular. One really representative name amongst them is that of Henry Vaughan, "the Silurist," whose "*Sacred Poems and Pious Ejaculations*" as edited by Henry Lyte (himself a hymn writer of rare felicity) reveal the "physician and singer" in admirable combination. Last century abounded in medical poets, didactic, lyrical and dramatic, of whom Goldsmith, Smollett and Akenside may be indicated as amongst the more prominent, whilst the century just closing surpasses all its predecessors in the number and to some extent, in the

he has made out a fair if not a very strong case in favour of his hypothesis, but that further inquiry must show whether it is correct or not.

From our Dead Selces to Higher Things By FREDERICK JAMES GALT, F.R.C.S., Author of "The Lord of Humanity" and other works London James Nisbet and Co 1893.—This is a wholesome book of its kind, and, whether the reader agree wholly or partially with the author or not, is worthy to be read in quiet moments. Of course the general theme bristles with difficulties if looked at from a philosophical point of view, or even from the standpoint of the religious disputant. But, accepting the current thought of orthodox believers in the Christian system, no serious exception is likely to be taken to the way in which the subject is presented. In discussing the various points offered for consideration the author has the advantage of possessing, by virtue of his calling, an intimate acquaintance with the frailties of human nature and with the struggle often required to be undergone by those who seek to attain a higher grade of moral excellence. The subject of the work, however, is scarcely suited for discussion in our pages, and, whilst according our sympathy with the purpose of the author, we must leave the criticism of his book to the theological controversialist.

Certifying Surgeon's Daily Report Book Manchester T. H. Hayhurst.—This little book has been designed by Dr James Holmes, hon. secretary of the Association of Certifying Factory Surgeons, and appears to be very well suited to the purpose it is intended to serve. The book is divided into four sections which are severally distinguished by the adoption of variously tinted paper, so that each section may be readily referred to. In the first section the number of cases is to be recorded, with age, sex, name of firm &c., the second is intended to record particulars of cases rejected, with reasons for rejection and the nature of manufacture for which the certificate was refused, and so on, in the third section space is reserved for a record of reports of accidents, for the name of the person injured and the nature of the injury sustained, finally, blank sheets are provided for the entry of general memoranda. For the purpose of assisting certifying surgeons in the work imposed upon them by the Legislature, we cannot doubt the book will be of distinct value. Probably some little modification in its arrangement may be suggested by further experience.

Analytical Records

FROM

THE LANCET LABORATORY

WALDEN'S EXTRACT OF BENNET

(R. W. WALDEN, EATON SQUARE, S.W.)

THIS preparation is evidently the genuine extract of the fourth stomach of the calf. It readily curdles cow's milk at blood heat and the resulting sweet whey may easily be decanted and subsequently treated with a sufficient quantity of milk sugar and new milk, so that its composition may be made to simulate mother's milk. The rennet powder is well adapted also for the preparation of junket, but from the certainty of its action and the ease with which it may be used it is more valuable for the former purpose. Being in the form of a dry powder, the curious ferment contained in it is less likely to undergo undesirable changes in keeping—a distinct advantage over the liquid preparation.

FRUIT SALT BAKING POWDER.

(W. G. DUNN AND CO., CHARTERHOUSE)

This powder is free from objectionable ingredients and more particularly alum. It simply contains well known salts

which when moistened interact and evolve carbonic acid gas. We protest against the use of alum in baking powder. The laws of the country do not allow alum to be used in bread flour or other foods, and although baking powder is not a food any more than are pepper, vinegar, and mustard it is solely and ostensibly made for no other purpose than for incorporating with certain foods with the object of rendering them porous and light.

ANGIER'S EMULSION OF EARTH OR ROCK OIL WITH HYPOPHOSPHITES OF LIME AND SODA.

(ANGIER CHEMICAL CO., BOSTON, U.S.A. AND 32, SNOW HILL, E.C.)

From a chemical point of view the idea of using a pure bland hydrocarbon as a vehicle for hypophosphites is decidedly advantageous, for the preservative properties of a hydrocarbon like petroleum are well known. As a matter of fact, we found in the above preparation the hypophosphites intact, whilst there was little fault to find with the state of the emulsion, which, under the microscope, was seen to consist of minute globules uniformly distributed. The condition of emulsion is destroyed on the addition of ether, especially in acid solution, and the hydrocarbon left on evaporation of the ether consisted of a semi solid fluorescent oil, becoming quite limpid at 34° C, and boiling above 300° C. That the hypophosphites exist as such was evident from the fact that the emulsion on ignition burnt with a weird looking greenish flame from the formation of phosphuretted hydrogen due to the reduction of the hypophosphites by the boiling hydrocarbon. The emulsion is perfectly neutral to test paper and gives but feeble evidence to the taste of the presence of petroleum. Petroleum has seldom been employed in this country for internal use, although it has been used both as a vehicle and a medicament in the United States. It has been administered in the treatment of affections of the air passages and for the relief of uterine disorders, its action being chiefly to allay local irritation. The oil used in this emulsion is according to our own experiments, specially refined and purified, and it may therefore be used with confidence if intended for internal administration. Apart from its stable character, there are other features possessed by a seven times purified hydrocarbon which will doubtless induce practitioners to give this interesting and novel preparation a trial.

BISCUITS CONTAINING SYR. FERRI PHOSPH. CO

(J. D. MARSHALL, 5 PICCADILLY ROAD S.W.)

There is nothing about the flavour of these biscuits to indicate the presence of an iron salt, on the contrary, they are very palatable and their texture is satisfactory. Each is stated to contain a teaspoonful dose of syr. ferri phosph. co. This statement is so far borne out by our examination, when the biscuits are soaked in water, for example, the solution is found to be distinctly acid, iron and phosphates being present according to chemical tests. Under the microscope it is evident that oatmeal and wheat flour form the basis of the biscuits. The addition of iron does not appear to alter the condition of the cereal proteins, for experiment showed a notable proportion of soluble nitrogenous matter.

New Inventions.

DEAN'S CLINICAL THERMOMETER.

THE instrument invented by Mr A. E. Dean, jun. 73, Hatton garden, has the novel feature in a clinical thermometer of the readings commencing at the upper part of the stem, away from the bulb. When an observation is taken it is therefore necessary to invert the thermometer, and the column of mercury which has been detached from the bulb and has passed the constriction flows down the stem to unite with a small quantity of mercury

Action of some Toxic Substances All these memoirs are interesting and will repay the study of those who have not already perused them

Manuel de Petite Chirurgie de A. Jamain Septième Edition, illustrée de 415 Figures intercalées dans le Texte. Par FÉLIX TERRIER, Professeur à la Faculté de Médecine de Paris, Chirurgien des Hôpitaux, et M. PÉRAIRE, Ancien Interne des Hôpitaux de Paris Paris F Alcan 1893

THIS is a very popular French text-book, which has held its place for many years. In preparing this new edition, Professor Terrier has been assisted by one of his pupils, Dr Péraire. Together they have made a careful revision of the text and have brought it well up to date. The various details of antiseptic and aseptic surgery are very carefully described in their application not only to wounds but to such matters of minor surgery as explorations of various kinds, catheterism and dentistry. Several methods of sterilising instruments and dressings are given, and in all pertaining to this part of the surgical art the book is thoroughly trustworthy. The English reader finds in it some things with which he is not familiar and misses others that he would surely find in any British text-book on minor surgery. For example, there is no reference to Sayre's method of treating fracture of the clavicle, or to Carr's excellent splint for fracture of the radius, or to Clover's or Ormsby's apparatus for the administration of chloroform and ether. It is unfamiliar, too, to find the bandages carried round the limbs the reverse way to that practised on this side of the Channel. But, as we have said, it is a capital manual, and worthy of a better binding than that which is called by the publisher "*un élégant cartonnage anglais*."

LIBRARY TABLE

The Shop Hours Act, 1892, with Notes and a Form. By JAMES ROBERT VERNAM MARCHANT, of Gray's Inn, Barrister at-Law London Effingham Wilson and Co 1892.—An Act which is based on the undoubted fact that "the health of many young persons employed in shops and warehouses is seriously injured by reason of the length of the period of employment" cannot be without interest to the members of the medical profession. It is curious to notice that whilst grown up working men are clamouring for legislation to restrict their work to eight hours a day, and whilst last year many candidates for Parliament were prepared to concede such legislation Parliament itself was occupied in passing the above-named Act, which is meant to protect young persons of either sex, that is, persons under the age of eighteen, from being employed in or about a shop for a longer period than seventy-four hours, including meal-times, in one week. The Act is an important one and is not so likely to remain a dead letter as previous Acts of the same sort. Inspectors may be appointed by town councils to see that the provisions of the Act are observed, and already the London County Council has made such appointments. The Act is not quite easy of construction, owing chiefly to the fact that many of the provisions of the Factory and Workshop Act, 1878, are incorporated with it, as Mr Marchant says, in a somewhat reckless way. It was a happy thought to put the Act into a compendious form and to give with the sections of it such explanations, by a competent lawyer, of the provisions of the Factory and Workshop Act as to make it intelligible to those interested in it, who must number many thousands. In an appendix the provisions of the Factory and Workshop Act of 1878 are given. A good index greatly facilitates reference. Mr Marchant has done his work well, and the volume makes a worthy addition to Wilson's legal and useful handy books.

Notes on the Newer Remedies their Therapeutic Applications and Modes of Administration. By DAVID CERNA,

M.D., Ph.D. Philadelphia W.B. Saunders 1893.—This is a very handy little book containing brief records of the therapeutic applications of the newer remedies. The plan followed is to give a brief account of the nature, the physical properties, therapeutic applications, and mode of administration of each new remedy in turn. Advisedly, the author has omitted all details of physiological action and all bibliographical references. This is perhaps to be regretted, as the result is that statements of unequal value seem to receive equal importance of treatment. In studying the growth of any new science much assistance in winnowing the chaff from the wheat can be derived from a passing reference to the source of the new statements. The author has done his work carefully and has compiled a very useful little book of reference, which is well up to date.

De la Cataracte Senile Historique, Causes, Prophylaxie et Traitement Médical. Par le Docteur A. FERRET Paris Société des Éditions Scientifiques Pp 131 1893.—This treatise commences with the history of senile cortical cataract and of the operations that have been undertaken for its removal. It appears to be an *avant-courier* of a larger work on ophthalmology that Dr Ferret is about to publish. He believes the term "cataract" to have been given to the affection by the Arab physicians who translated the works of the Alexandrian Greeks. They used a periphrasis signifying a fall of water in the eyes as a synonym of the terms employed by Galen and his successors to designate the disease. In the barbarous Latin of the Middle Ages a fall of water was a cataract, and the Salernian physicians, who received their medical education from the Arabs, accepted the term and this led to its general adoption. The determination of the methods of operation and of the indications for operation the author considers were satisfactorily laid down by the French surgeons of the last century, and he contends that other methods of cure besides that by operation have been too much neglected. Dr Ferret then proceeds to unfold his view of the etiology of this form of cataract. He distinguishes two forms of senile cataract, the hard nuclear and the soft cortical form, and states that he was led to the opinions he holds by having observed in a visit to two islands in the south of France that in one there were twenty-one cases of cortical cataract amongst 6000 inhabitants, whilst in the other there were only three in 7000 inhabitants. In seeking to explain this great difference in the proportion of cases he was unable to find any reason for it in the diet, clothing or habits of the people except that in the island where the cases were most numerous there were saline marshes. Further observation led him to the conclusion that a condition of the blood which he terms "hyper-chloræmia" is eminently likely to lead to cortical cataract. He supports his view by pointing out that the Arabs and the Kabyles of Algeria enjoy immunity from cataract and that these tribes consume very little salt in their food and considers that cataract is diminishing in the country population of Paris because they live much less exclusively on salted provisions than formerly, whilst the consumption of the potato, by introducing into the system the salts of potassium which replace the salts of sodium, has been an additional factor in reducing the frequency of cataract. Moreover, he has been able to induce cataract in rabbits by subjecting them to a diet in which much salt was added to their food, and he refers to the experiments of Kunde, in which the lenses of frogs were rendered opaque by introducing salt beneath the skin of a part of their bodies kept above the surface of the water. The final stage of the senile cortical cataract is the Morgagnian cataract, which is certainly rare. It is difficult to discuss Dr Ferret's views in the absence of any data in regard to the relative frequency of cataract in those tribes which do and do not use salt freely, and all that can at present be said upon the subject is that

THE LANCET.

LONDON SATURDAY, MARCH 18, 1893

IN the Croonian Lecture on the Position of Pathology amongst the Biological Sciences, Professor VIRCHOW, who stands in the very first rank of the investigators of this century who have utilised the general principles of biology in the elucidation of pathological problems, and who has offered to biologists as a result of his pathological investigations many and important biological facts, brings before us with exceedingly great clearness the wonderful advances that have been made in the study of pathology and biology during the last fifty years. It was fitting that the Royal Society, before which, over 300 years ago, LEEUWENHOEK presented the results of his investigations made with the aid of his own microscopes, should last year have done honour both to itself and to the great exponent of cellular pathology by awarding the Copley medal to one of the most brilliant, and at the same time most patient, investigators and thinkers of our time. RUDOLF VIRCHOW is not merely the exponent of cellular pathology or the initiator of a philosophical system of medicine, he is a profound thinker, an accurate observer and patient investigator, he has modified, even transformed, our conception of disease, which is no longer merely a thing of humors, nor some entity which, having found its way into the body, there maintains a kind of symbiotic existence, whilst, most important of all, he has urged that whatever may have to do with the biological history of an organism must necessarily have an intimate bearing on all pathological questions relating to that organism. RUDOLF VIRCHOW (coming immediately after JOHANNES MÜLLER, whose work on the intimate structure and form of morbid tumours opened out the possibilities of the application of the microscope to pathology and medicine, and SCHWANN, who had so recently expounded his cell theory of the structure of certain of the animal tissues) at once commenced that study of tissues and cells as a result of which he was able, after long and careful application and discussion, not only to extend the cell theory and to get rid of the spontaneous generation theory—a theory put forward by SCHWANN, BENNETT and other physiologists in support of the dogma that animal cells were formed by a kind of crystallisation or precipitation process from what they described as primitive blastema. Upon VIRCHOW also devolved the task of correcting and extending the inductions drawn by JOHN HUNTER from his own careful and accurate observations, for although HUNTER in point of time came so many years before the blastema theory, which indeed was in great part founded on his observations, he himself was far in advance of those who initiated and upheld it. In the first volume of his *Archiv*, VIRCHOW foreshadows as it were, in his description of medical science and its future, what his own life's work has since proved to be, he says. Let us not deceive ourselves about the condition of medicine, minds are undoubtedly exhausted by the numerous hypothetical systems which again and again are cast aside, only

however, to be replaced by fresh ones. It may be that after a few more invasions this condition of unrest will have gone by, and it will be recognised that only quiet industrious and persevering work, the true work of observation or experiment, possesses lasting value. Pathological physiology will then gradually be developed, not as the production of a few heated brains, but as that of many patient investigators that pathological physiology which is the citadel of scientific medicine, of which pathological anatomy and clinical investigation are merely the outworks. It is this practical but philosophical study of pathology that has carried VIRCHOW'S school so far ahead of the schools of pathology. Pathology is, indeed, he holds, merely a phase of biology, all active life in protoplasm is maintained and manifested as the result of the irritability of that protoplasm, the manifestations varying according to the special differentiation of the cell, just as the manifestations of disease are simply those of cells living under abnormal or irregular conditions. In speaking of VIRCHOW'S school, one must not do him the injustice of ascribing to him the desire to found a school, using that term in its ordinary sense. His is not a school of creeds or beliefs, of dogmas or of unsupported assertions—it is rather, as he said of that of MÜLLER, one of the methods of experimentation, of observation, the pathologist calling in to his aid and utilising freely the results that have been obtained in physiology, chemistry and botany, and similar sciences. He it was who applied to pathology those methods which VESALIUS and HARVEY had applied to anatomy and physiology, he threw overboard all philosophical theories and pinned down himself and his pupils to hard matters of fact, speculation, unless based on a solid foundation, he spurned as unworthy of the consideration of men who have at command the facts obtainable by modern methods of investigation. His whole energies have been devoted to putting pathology and medicine upon such a footing that they may no longer be mere empirical arts, but may take high rank amongst even the more exact of the natural sciences. Whilst accepting all this, however, no man has fought more strongly for the view that pathology must be investigated by pathologists, and that its study involves something more than a knowledge of normal physiology, without which, nevertheless, no pathology worthy of the name can ever be built up, and, whilst accepting it as proved that the morbid changes in organs, tissues and cells are indicated by a study of pathological anatomy, he has always taught most earnestly and persistently that, in order to obtain an exact knowledge of the processes of disease, it is necessary to go back to pathological physiology—nay it might be said pathological biology in the widest sense of the term—so that, although, as in the case of normal anatomy, we must in the first place rely for our exact knowledge on dissection and study of the dead subject, the problems of general or physiological pathology can only be elucidated by having recourse to careful experiment and accurate clinical observation. Anatomy without physiology was looked upon as a science which could only be advanced by the aid of a dissecting knife, but anatomy considered as the study of the material medium through which function and the manifestation of life are made becomes a much more real and interesting if more complicated, study.

It has sometimes been said that VIRCHOW owed his ability

contained in a reservoir at the peripheral extremity of the tube. By this device no index is needed, and having tried the instrument on several occasions we can testify to the

accuracy of its record, but another advantage is claimed for it, which, when physicians get accustomed to its use, will be certain to be appreciated. Thus it can be "set" with very much less shaking than the ordinary clinical thermometer, owing to the reservoir of mercury in the upper end being distinct from the bulb. This permits of the presence of a long column of mercury in the stem whenever the registering column is being shaken back into the bulb. With low readings the registering column must of necessity be short, and if there be no reserve of mercury behind it there can only in that case be a short column to give rise to the centrifugal force which drives it home, which requires much shaking to be effectual. In this instrument, even with very low readings, it is much easier to send the registering column home and with much gentler shaking than is ordinarily needed. It may be added that the reservoir contains exactly enough mercury to fill the stem, so that it is not difficult to determine when enough mercury has been thrown back into the bulb. It may be added that the top of the tube is of smaller dimension, to allow of it being firmly held in the operation of shaking back the column.

HYPOGASTRIC CEINTURE OR UTERINE SUPPORT FOR HORSEWOMEN

THIS consists simply of a cushion somewhat resembling two pads of a hernial truss joined together and placed over the hypogastrium, being retained in position by a couple of belts passing round and crossed over the sacrum and fixed in front with an indiarubber covered strap round each thigh. This contrivance will prove of use to horsewomen who experience uneasiness in the hunting field on taking a leap. By its continuous pressure it steadies the pelvic viscera. It is also valuable in cases of threatened hernia in either sex, as it supports the external abdominal rings. It is made by Mr Huxley, 15 Old Cavendish street, W.

FOUL CISTERNs, CONTAMINATED WELLS, AND INSUFFICIENCY OF PRESSURE

In an able and instructive report recently presented to the St George's Vestry, Southwark, Dr F J Waldo, the medical officer of health for the district, deals with the evils that may arise from the storage of water in cisterns, from the drinking of water from polluted wells, and from the existence of an inconstant and insufficient supply. All three evils evidently exist in the parish alluded to, according to the facts revealed in the report. Commencing operations at the artisans' dwellings in the district, with the assistance of two sanitary inspectors, Dr Waldo found that a large number of the drinking-water cisterns—nearly always placed on the roofs, which are often utilised as drying grounds for clothes—were either incompletely or imperfectly covered. In most cases the cisterns were badly placed, with their tops often within six, four and a half, three, and two and a half feet only from the free vents of the soil pipes. The ventilators were working freely and gave unmistakable evidence of their contents. The water in the cisterns was frequently filthy, containing in some instances offensive decaying and decayed vegetable growth measuring two inches in depth, whilst the walls of the cisterns were covered with black slimy mud one third of an inch in thickness. A bundle of advertising pamphlets, setting forth the anti-septic virtues of a certain mixture containing borax, balls of wood shavings, bricks, stones, pieces of cistern

covers and a live leech were amongst the foreign bodies found in the cisterns. Dr Waldo has found a strong argument during his inspection in favour of the establishment of baths and washhouses in the parish of St George's. He has seen boys with their shoes and socks off and trousers tucked up in close proximity to cisterns, and he has gained evidence of a youth having washed his face and hands with soap in a cistern the water from which was the domestic supply of the unsuspecting tenants below. Drinking-water cisterns are frequently placed in inaccessible places, often above waterclosets and in areas where the water is liable to be contaminated by offensive and injurious emanations. Samples of water taken from the shallow pump wells of the district were submitted to Dr Muter, the public analyst for the district, for analysis. Each and all proved to be highly dangerous to health and largely charged with sewage and other deleterious matter. Eleven surface pump wells that remained in the parish have, with the exception of one, been either closed or safeguarded, the use of the latter having been compulsorily restricted for manufacturing and washing purposes only. Proceedings were taken against two owners who refused to close their wells, and as they appear to be the first prosecutions heard under the Public Health (London) Act they are of interest. In the first case the liberty of the subject was upheld against the sanitary action of the vestry, costs being allowed. The second case was saved by a cross-examination eliciting the fact from the owner that he had been in the habit of using the water for many years past and that he was still alive. More than this, a neighbouring publican had been in the habit of using the water for "mixing down gin." An order was made, however, for the closure of the well during one month, so that in the meantime it could be put into such a condition that in future it might give a pure in place of an impure water—a consummation which, as Dr Waldo adds, owing to the nature of the surroundings, is an impossibility. The report further contains some remarks relative to the insufficiency and inconstancy of the water supply in the districts served by the Southwark and Vauxhall Water Company. The vestry are taking active steps to remedy the evils thus exposed, and it would be well if all other authorities could be induced to conduct a similar inquiry, to be followed by the adoption of equally active measures.

Cisterns, abominable as they are, cannot entirely be done away with, but water intended for drinking purposes should not be allowed to stagnate, and where such is the case the pressure of legislation should be brought to bear upon the companies to compel them to provide a drinking supply direct from the rising main. As Dr Waldo has suggested—a suggestion which has been carried into effect with marked success—a duplicate pipe, conveying the water from the cistern in time of need—as in frost or when repairs are taking place—should, in addition, be provided. It is to be hoped that all evidence gained on a house to house inspection of the metropolitan districts as to the storage, constancy and efficiency of the water-supply—such as that recently conducted by the medical officer of health for St. George's, Southwark—will find a place in the mass of information that is now before the Royal Commission.

MEDICAL MAGISTRATE—The Lord Chancellor has added the name of Mr John Jackson, M R C S, L R C P, Edin., of Somerby, near Oakham, to the roll of Justices of the Peace for the county of Leicester.

UNIVERSITY OF EDINBURGH—On Tuesday last a meeting of the General Council was held to consider the draft ordinances recently issued by the Scottish Universities Commissioners on the financial arrangements of the Universities. Mr Taylor Innes pointed out two faults in the report of the standing committee of the Council with regard to the present system of the professorate—viz., the want of a minimum and the want of a maximum the existence in some cases of classes too large and of emoluments too high. Dr Scott Dalgleish said the medical faculty had been left with its twelve professors as it was fifty years ago. Each professor in the Faculty of Arts received on an average the fees of fifty students, whilst in the Faculty of Medicine each professor received on an average the fees of 150 students. If there were surplus fees in that faculty, they ought, he said, to be applied to the creation of new chairs and to the improvement of the machinery for original research.

duct in the business with a perfectly impartial mind, he had not discovered the least room for suspicion. He was able to say frankly to the House that he did not believe, so far as his opportunity of judging went, that the merits of the Connemara case had anything to do with the action of the Director General of the Army Medical Department." We dwell upon this, however, because it seems to us that a high minded sensitive man, smarting under imputations of a cruel kind that he knew to be entirely false, might, rightly or wrongly, be led to infer that some reasons, of which he knew nothing, existed in the background for what probably seemed to him at the time an arbitrary course on the part of those from whom he would naturally expect sympathy, advice and protection until all the facts could be established one way or the other. It is unnecessary, and would be tedious, to detail at length the subsequent course of events in this case, and unless so stated they would not be easily comprehended. Any errors into which Surgeon Major BRIGGS subsequently fell appear, after all, to have arisen from a want of judgment and proper information as to the position in which he stood. The matter, as far as we can judge, appears to have resolved itself entirely into one of military discipline. The Secretary of State for War having intimated his willingness to reinstate Surgeon Major BRIGGS on his withdrawing and expressing regret for the letter he had written, and that assurance having been given Mr LOCKWOOD withdrew his motion.

It is rumoured, and the rumour gains strength, that the sanitary progress of rural Scotland is being threatened by hindrance from an entirely unexpected quarter. When the Local Government Act was passed in 1889 one of its clauses was to the effect that each county should appoint a medical officer of health and sanitary inspector, neither of whom should be allowed to engage in any other work without the express written consent of the County Council. The clause was an admirable one, and the exception was obviously intended to meet the case of isolated counties like Orkney and Shetland or Bute and Arran, too small to require the whole time of sanitary officials and so situated as to be unable to combine with other counties. Nevertheless, a few other counties did, without any such excuse, propose to escape from threatened sanitation through the loophole left in the section in question. Happily, however, this was in most cases successfully circumvented through the operation of another Act of Parliament. Under the Local Taxation (Customs and Excise) Act the sum of £15,000 per annum was set aside as a contribution to the payment of the salaries of the sanitary officials employed by the Scotch local authorities. The grants from this fund were to be made subject to such regulations as might from time to time be issued by the Secretary for Scotland. Acting under the advice of the Board of Supervision, the Marquis of LOTHIAN, the then Secretary framed regulations which excluded from participation in the grant counties whose sanitary equipment was held to be unsatisfactory, and with such exceptions as already mentioned, it was laid down that counties whose medical officers and inspectors had been engaged to give only a fraction of their time to the work were unsatisfactory as to their arrangements and should have no share in the £15,000.

The regulation was obviously a wise one, and, we have no doubt, had the effect of confirming many councils in their policy of sanitary thoroughness and of directing doubtful counties into a proper course. The sum of £15,000 may not seem large, but neither, unfortunately, are Scotch medical officers' salaries, and the result is that in the year 1892 the properly equipped counties have had recouped to them fully one half not only of the salaries, but also of the travelling expenses of their sanitary officials, whilst the recalcitrant counties have received nothing. It is with dismay, therefore, that we hear that there is now considerable risk of a reversal of this policy and of a frittering away of the money amongst deserving and undeserving counties alike, and, of course, with a fixed amount to operate on, whatever enters the pockets of the latter comes out of the pockets of the former. But the actual amount wasted in this way will be of little consequence compared with the principle involved, and we are quite sure that nothing is further from the purpose of Sir GEORGE TREVELYAN than to take anything in the nature of retrograde sanitary action. The appreciation with which he has received recent deputations on public health questions and the breadth of view which he has manifested regarding the problems put before him indicate how fully alive he is to the sanitary needs of the northern kingdom. We venture to hope therefore that before actually deciding on the course to be pursued he will at least ascertain the views of some of the medical men who are at present members of the House of Commons and several of whom are both Scotch themselves and representatives of Scotch constituencies. So unwise, indeed, would be the step which rumour says is about to be taken that we have no hesitation in prophesying that he will find the skilled opinion which he can so easily consult unanimously opposed to the project. Meanwhile, let us give Sir GEORGE TREVELYAN a single hypothetical illustration of the objections to the system which he is thought to favour. In a county a question may arise as to the alleged insanitary condition of a dairy farm. The premises are to be inspected by a subcommittee, consisting perhaps of only one member of a local authority. He reports favourably. But a medical report is also wanted. It is obtained and is likewise favourable. However, the subcommittee may turn out to be the paid factor of the landlord, to whom the farm belongs and the medical reporter a heavy private medical attendant. Such a favourable report might be perfectly correct and honestly given, but the system is obviously altogether wrong and surely is not one which the Secretary for Scotland should subsidise out of the public funds.

TESTIMONIAL. — A distinguished gathering, assembled on Saturday last at the Winter Gardens Folkestone, to present Dr R. L. Bowles with a testimonial on the occasion of his leaving Folkestone. The presentation consisted of a large silver bowl, a silver tea tray, and a set of embossed silver gilt goblets and claret jug, the whole costing about £300. The Mayor in presenting the testimonial together with an illuminated address signed by several hundreds of subscribers, briefly sketched Dr Bowles' career in Folkestone during the last forty years. Dr Bowles, in reply, expressed his gratification at the presence of such a large number of old friends, and thanked them for the handsome testimonial and the good wishes which accompanied it.

to set forth his cellular theory of pathology to the investigations of earlier biological workers, but it has been well said that "the discoverer of a scientific fact is not he who has divined it, but he who has proved it." Pathologists of to-day might well write these words in letters of gold and keep them constantly before their eyes. VIRCHOW proved the cellular theory. Knowing, as we do, how fundamental to modern pathology is the dictum, "*Omnis cellula e cellula*," it is difficult to conceive of an older system of pathology as being based on anything more solid than theory. The origin of tumours, the alterations in the blood, the process of inflammation, of degeneration, had no foundation on observed facts, we had a pathology of symptoms, but no true pathology—a pathology "of humors and solids," of primitive blastemas and of spontaneous generations, but all vague and unsatisfactory. It was only when VIRCHOW applied the Baconian method to the problems with which pathologists were then dealing and to the enormous store of material that had been collected by pathological anatomists that something like order and definite form could be evolved from the chaos left by the various teachings of the "schools." The ontology of disease had superseded humoral pathology, and it in turn had to give way to the physiology of disease. Cellular pathology still maintains its ground, and all that further investigation has done has been to extend and amplify the importance of cellular pathology as originally advanced by VIRCHOW. From his first works on arteritis and phlebitis to his most recent contributions on "Transformation and Descent" and their relation to disease there is the same idea running through all his writings—the identity of normal and pathological processes, manifested, however, under different conditions. How generous Professor VIRCHOW is to those pioneers of pathology and biology in this country those who read his lecture as given in our columns will understand, and we venture to put into words our distinguished visitor's idea that knowledge belongs to no country and that no one who is engaged in the study of nature and attempting to elucidate her mysteries can be claimed for any one nationality. The Royal Society may well hold that, as it has made Professor VIRCHOW an honorary member, it has put in a claim for a share in the triumph of a man of whom Germany may well be proud. Those who read between the lines in Professor VIRCHOW'S address, and who, if they have not already done so, go through his published work even without attempting to master that of his best pupils, will appreciate the enormous difference in the "spirits" of pathology of 1853 and 1893. To the newer pathology, cellular pathology, as expounded by Professor VIRCHOW, we are indebted in great measure for the wonderful advances that have been made in the treatment of disease, and for the still greater promise that is held out for the future.

THE case of Surgeon Major BRIGGS was very ably and fully brought before the House of Commons by Mr LOCKWOOD on the motion to go into Committee of Supply on the Army Estimates. Mr LOCKWOOD'S notice was to call attention to this officer's case, and to move for a select committee to inquire into the refusal to reinstate him. A long discussion followed, in which Mr CAMPBELL BANNERMAN and Dr FARQUHARSON took part, and which ultimately terminated in Mr LOCKWOOD'S declaring that Surgeon Major BRIGGS was

willing to express regret for a letter he had written and to ask leave to withdraw it. Here, it may be said, in the terms used by our neighbours the French, "the incident closed." But we cannot help expressing great sympathy with Surgeon Major BRIGGS. Most people, too, whilst glad to learn that this officer is to be reinstated, will not regret that publicity has been given to the case. We take our information entirely from the report of the discussion in *The Times*, and simply record the impressions derived from the perusal of that report. Here was a medical officer who had an unblemished record. He had rendered excellent and even distinguished service during his military career, not only in connexion with his profession, but in the field, in various trying expeditions, and his services in these respects had been recognised in despatches. In 1886 he had the very grave misfortune, as it turned out, to be appointed medical officer on the staff of the then Governor of Madras, Lord CONNEMARA. Into all the painful circumstances which led to the lawsuit instituted by Lady CONNEMARA in the Divorce Division of the High Court of Justice there is no need to enter. Let it suffice that Surgeon Major BRIGGS was placed in the most trying position possible and that he acted throughout with a chivalric and fastidious sense of honour. He felt that it was his paramount duty to others, to himself, and to the honour and good repute of the service to which he belonged to shirk no inquiry but to court it, and he must have looked forward with keen anxiety to the trial in a court of law where he could establish, once for all, his entire innocence of gross charges and imputations which involved himself and others. In this he entirely succeeded, and his course of action under the circumstances in which he was placed subsequently met with a highly flattering expression of approval in the House of Commons by the late Secretary for War. But, in order to fulfil a duty which he could not resist and was bound as a gentleman to perform, he had beforehand to make the great sacrifice of resigning his commission rather than go abroad when ordered. And it is at this stage that we fail to appreciate the necessity of his being placed in that position. How was it that he was not directed as to the proper course for him to adopt under the circumstances, or why did he not himself obtain a subpoena or some other legal or official proof, or make an affidavit that his presence in England was, pending the trial, absolutely essential? A request based upon something of this sort—to be allowed to remain in order to appear at the trial—would surely have been held sufficient for the purpose by the military authorities. It seems surprising that, under the circumstances, such a course was not indicated to Surgeon Major BRIGGS by his military superiors if it was necessary for them to be armed with some specific documentary proof of his *bona fides* and of the exact nature of his requirements as to the probable time that his presence in England would be necessary for the termination of the legal proceedings. Mr CAMPBELL BANNERMAN was careful to explain, however, that, as far as he and the War Office were concerned, the Connemara case had nothing to do with the case of Surgeon Major BRIGGS. The War Minister went on to say "Whether the conduct of the Director General of the Army Medical Department was in all respects judicious and proper and regular was another matter, but, having gone into his con-

certainly which is common to most other men. Add to this the fact that every day he lives brings him in contact with much that is anxious and responsible in work, and we need be at no loss to explain why the freedom blended with order which are found on shipboard constitute for him a restorative influence of much value. We admit that there are drawbacks to travel by sea. Its familiar physical disturbances need only be mentioned, its occasional monotony cannot be denied. Its constant subjection to the action of climate, season and weather must now and then prove depressing. Yet withal the amateur sailor, if in fair health, finds in it ample means of recreation. He may not, perhaps be so fortunate as a member of the profession—Dr Fyfe—who lately closed a series of published letters descriptive of a yachting cruise round the world, extending over nearly two years and unmarked by any case of illness or serious injury. For all purposes of the ordinary holiday, however, a much briefer voyage will suffice, and the season is now near at hand when from every considerable port on our shores it will be possible by means of a well appointed passenger steamer service to visit other shores or to circumnavigate our own. The accommodation provided even on the shorter routes is often excellent, though better adapted, perhaps, for travellers of the sterner than of the fairer sex. We feel certain, therefore, that a pleasure trip of the kind indicated will commend itself as the season advances to any of our medical brethren who may choose in this way to combine the enjoyment of well-earned rest with the interest of novelty amid the purest and freshest atmospheric surroundings.

SANITARY REGISTRATION BILL, 1893

THE word "sanitary" is by degrees having attached to it a meaning more limited than heretofore. In recent times we have heard of the 'sanitary arrangements' of a house, as appertaining peculiarly to the waterclosets and drains, an Act of Parliament has adopted the slang and uses the expression "sanitary convenience" in a special sense, the interpretation clause of the Act telling us that this expression includes 'urinals, waterclosets, earth closets, privies, and any similar conveniences.' Then, again, we have the expression 'sanitary engineer' as descriptive of a class of persons who claim to know more about waterclosets, drains and their belongings than other people, now we have a Bill before us which proposes to create "licentiates in sanitary practice," and when the contents of the Bill come to be understood we find that these gentlemen are to be licentiates of the practice of waterclosets and drains. In these days of specialism many people perhaps will see no objection if any architect should think fit to limit his practice to waterclosets and drains nor need we raise any objection to the Institute of British Architects if it desires to do so conferring some special and distinctive title upon any member of that body whose knowledge of waterclosets and drains may in any high degree excel that of his fellows. But we have a strong objection to and do protest against, the principle embodied in the Bill that, provided the waterclosets and drains &c. of a house are constructed in a particular manner, the building is entitled to be certified as in a satisfactory sanitary condition, and, further we protest against the proposal to constitute a large army of so-called licentiates who are to be empowered to give a statutory certificate of the sanitary condition of a house on such insufficient grounds. It is quite obvious that the Bill has been prepared by gentlemen who have been misled by the circumstances we have described, and who in engaging in "sanitary practice in this modern and very limited sense, are entirely oblivious of the fact that they are only touching a few of the conditions of a house which may affect health. The Bill is the outcome of want of knowledge and is bad in principle. If it passed it would create a new class of persons

many of them probably very incompetent, whose certificates would have to be accepted by sanitary authorities no discretion being left to the authorities to determine whether work done under the supervision of these people was or was not adequately carried out, and it would hand over to these licentiates in waterclosets and drains every unfortunate house-owner and require him to satisfy them as to the condition of his house. In writing thus, we are not failing to recognise the importance and indeed the necessity of all house drainage being improved so far as is required to satisfy present requirements, but this, we hold, should be done through the intervention of the recognised sanitary authority, who will act under a larger sense of responsibility than would any individual contemplated in the Bill.

THE ROYAL FAMILY AND THE PROTECTION OF CHILDREN

NOTHING can be more gratifying to all who have at heart the welfare of children in this country than the emphatic manner in which the Society organised for their protection against cruelty has been supported by the Royal Family. The terms of warm and unreserved commendation in which the work hitherto carried on by the Society was described at its recent dinner by his Royal Highness the Duke of York were, we need hardly say, as creditable to the speaker's own feeling and judgment as to the cause of which he was the willing advocate. Several members of the Legislature and many other influential persons have repeatedly spoken to a like purpose, admitting at once the unfortunate necessity for the Society's efforts and the moderation and success with which these have been exerted. We are pleased to note that Her Majesty the Queen, by a double contribution to the Society's exchequer has given the most unmistakable proof of her sympathy with its object and its methods. These facts are such as may well be regarded by all classes of the community as of the happiest omen. They augur well for the continuance of labours the urgent need of which is also sufficiently evident from the measure lately introduced by Sir Richard Webster for amending the Bill for the Protection of Children and from the fact that over 900 cases of undoubted cruelty were during last year brought to light in England alone by the agents of the Society.

SIMULTANEOUS AFFECTION OF THE LACRYMAL AND PAROTID GLANDS

DR. ERNST FUCHS, Professor of Ophthalmology in Vienna, has published an account of a case where disease of the lacrymal glands was associated with disease of the parotid glands. The patient was a man aged sixty one who, after suffering for four months from swollen eyelids noticed that a tumour was forming below the ear. When seen a month later both upper lids were found to be pressed forward by a tumour in the external and upper portion of the orbit, evidently an enlargement of the lacrymal gland. Both parotid glands were also enlarged, forming smooth tumours three or four centimetres in extent, resting on the ascending ramus of the lower jaw and raising the lobule of the ear. None of the tumours showed any signs of inflammation, and there was no pain or tenderness in any of them. Treatment was without avail, and at the end of a year they had slightly increased. A fragment excised from one of the lacrymal glands for examination showed large and small nodules like those in a lipoma and much resembling the lymphoid tissue of the follicles in trachoma. It appeared probable that the tumour had originated from the interstitial connective tissue, as no glandular substance was found. Professor Fuchs has only been able to find three cases in medical literature in which the lacrymal and parotid glands were simultaneously affected. One, reported by Kaltenhoff,

Annotations.

"Ne quid nimis"

PROFESSOR VIRCHOW

PROFESSOR VIRCHOW, whose lecture at the Royal Society on Thursday we have the satisfaction of being able to publish in our present issue, will probably remain with us until the 27th inst. After the delivery of the Croonian lecture he was entertained at a banquet, at which Lord Kelvin presided. During his stay in England our distinguished guest will be the recipient of many honours, amongst which may be enumerated the honorary degrees of Oxford and Cambridge, the former of which will be conferred on the 23rd inst and the latter on the 21st. The council of the Irish Medical Graduates' Association have invited Professor Virchow to accept the honorary membership of that body, and that ceremony will take place to day (Friday). He will be the guest whilst in London of several of the prominent leaders in medicine and literature, amongst whom may be mentioned Sir James Paget, Sir Joseph Lister, and Sir John Lubbock, whilst in Cambridge he will be entertained by Professor Roy, and whilst in Oxford by the Master of Pembroke College and Professor Burdon Sanderson.

THE QUEEN'S VISIT TO FLORENCE

AN Italian correspondent writes "Rarely has Queen Victoria's vernal *villeggiatura* been undertaken in circumstances apparently so auspicious. The city in whose neighbourhood Her Majesty is shortly to sojourn has special attractions for the Queen, over and above those which draw to it perennial pilgrimages from the worlds of literature and art. There it was that many of the brightest, most profitable hours of 'Albert the Good's' early manhood were spent, there it was that he studied music and painting, Italian history, poetry and fine art, that he made excursions into the romantic neighbourhood on horseback or on foot and imbibed the lessons in political development in which the Tuscan Commonwealth, whether as republic or as duchy, abounds. In retracing his steps, Her Majesty, five years ago, enjoyed the pleasing melancholy, so dear to all sympathetic natures which have long passed the 'mezzo del cammin di nostra vita,' whilst equally benefiting by the contemplation of the same artistic *chefs d'œuvre* and by visiting the same scenes made memorable by historical or literary association. The climate, too, of Florence and Fiesole (in which latter parish Her Majesty really resided) was in itself an exhilarating and restorative influence—the pure air, continually refreshed from the neighbouring Apennines being nowhere more enjoyable than in the Villa Palmieri, in which the Queen had fixed her abode. Then, again, the health conditions of city and suburb, exceptionally favourable during her sojourn, made all Her Majesty's movements as free and unrestrained as immunity from disease, epidemic or sporadic, could render them, whilst the demeanour of the Florentines, respectful and unobtrusive, promoted the convenience of their Royal guest in a manner peculiarly gratifying to her in the circumstances of her visit. In all these respects this second sojourn of Her Majesty in Florence will be even more happily ordered than her first—the health of the city and neighbourhood being better than it has been known to be for many years, the water supply having received more effective supervision and the various sanitary conditions of the place put upon a more satisfactory footing. As at present arranged, Queen Victoria will prolong her residence at the Villa Palmieri considerably beyond the duration of her last visit, and will thus have fuller and more favourable opportunity for really enjoying and benefiting

by that most delightful experience—a Tuscan *primavera* or spring tide. As before, or even more vigilantly than before, the Florentine Municipio will exert itself to enhance Her Majesty's convenience throughout the term of her sojourn in every possible way, the lighting and other police regulations between the city and her villa being placed under a surveillance which, truth to tell, the good Florentines are all too unaccustomed. Royal and Imperial visits will also be paid to Her Majesty during her residence at the Villa Palmieri, and a series of entertainments, in which Verdi and Mascagni are expected to take a personal interest, are already in contemplation. Previous disappointments as to the coming of their Royal guest have stimulated the official world of Florence and Tuscany to redoubled efforts towards ensuring success for Her Majesty's approaching visit, and its preparations, already achieved or in course of completion, give promise of results in all respects satisfactory to both visitor and hosts."

HOODED VANS IN LONDON

WE are glad to see that in the House of Commons last week Mr Parker Smith asked the Home Secretary whether he could state the number of accidents caused by hooded vans in London during the year, whether vans in which the driver was entirely surrounded on three sides were permitted in any other city in the country, and whether he would take measures to ensure that proper precautions were insisted on by which, in all vehicles plying the streets, the driver should be able to have a sufficient view at the sides to prevent danger of collision with other vehicles or of running over foot passengers. Mr Asquith replied that, with reference to the first and second paragraphs of the hon. member's question, he was unable to give an answer, but that he was in communication with the Commissioner of Police. With reference to the third paragraph, he stated that the police have no power to enforce regulations requiring the driver of a van to be seated on any particular part of it or that the van should be furnished with windows. It is to be hoped that the result of Mr Asquith's consultation with the Commissioner of Police may lead to some action being taken in this matter. We can see no reason why the law should not require that the drivers of these hooded vans should be so placed as to command an uninterrupted view of the traffic. There would doubtless be a great outcry if the drivers of "hansoms" were permitted to direct their cabs from the interior of the vehicles, yet the position would be less rather than more absurd than that of the drivers of hooded vans, seeing that hansom cabs are invariably provided with windows at the sides. It may, perhaps, be urged that the drivers require protection from bad weather, but we fail to see, if they were compelled to be seated outside their vans, that they would be in any worse plight than the drivers of private carriages, cabs, omnibuses *et id genus omne*.

HOLIDAYS AT SEA

A VARIETY of circumstances combine to invest the holiday spent at sea under ordinarily favourable conditions with a composite charm which is something peculiar in itself, and which must be felt in order to be rightly appreciated. The panoramic survey of surrounding nature, the unsurpassed purity of the atmosphere, the society of agreeable companions, the regularity of daily life, and, finally, the fact that physical rest is compelled whilst access to business is forbidden by the existing natural conditions, unite in forming a total of leisured recreation which requires no fitter prelude than hard work for its enjoyment. For all the reasons above given a week or two so spent should furnish the busy practitioner with an admirably suitable method of relaxation. Interruption and irregularity are at all times characteristic of his calling. Neither in regard to sleep, meals or home life does he enjoy the privilege of

some satisfaction to him to reflect that by giving publicity to the story of his grievance he will have put other readers of THE LANCET on their guard. We cannot ensure that our efforts to exercise such censorship as will exclude from our columns every objectionable advertisement, however seemingly innocent will invariably be successful, but we can assure our readers that we leave no stone unturned to effect this end—indeed there is probably no journal published in which more care is exercised in this respect

THE HEALTH OF MR. GLADSTONE

CONSIDERABLE excitement has been caused by the recent announcement that the Premier was suffering from illness. In view of his advanced age and the great strain to which his work in the House of Commons must necessarily subject him, anxiety is only too likely to be aroused. We are glad therefore, to be able to state that his ailment is simply an ordinary "cold," with slight elevation of temperature and some increased frequency of pulse. It is reassuring, moreover, to add that he has none of the characteristic symptoms of influenza, although that disease has been prevalent in his household.

PREVALENCE OF FEVER

A SLIGHT increase in the number of scarlet fever cases notified was apparent during the week ending Feb. 4th. Rather more than 1000 cases were notified, of which London contributed more than a third, Liverpool, Leicester, Sheffield and West Ham were responsible for most of the rest. Diphtheria also showed a decline or some 40 cases, but London contributed about one half of the total. Next to London, Liverpool had the most cases of enteric fever. The fatality from influenza continues to increase. Last week 41 deaths occurred, the average of the previous three weeks having been 27.

THE INTERNATIONAL MEDICAL CONGRESS

AN Italian correspondent, under date, Rome March 10th, writes. The arrangements for the 'Esposizione Internazionale di Medicina e di Igiene' in connexion with the International Congress are rapidly approaching completion. As already stated, the Roman Town Council has set apart for it the magnificent Palazzo delle Belle Arti (the permanent Fine Art Exhibition) in the Via Nazionale and within reasonable distance of the Policlinico where the Congress will hold its sittings. The Exhibition itself will be open from Sept. 15th to Oct. 15th, and even, if necessary, for some time longer. It will have special annexes devoted to the Red Cross and to the Bacteriological and Hydrological Sections. It will comprise the following classes: 1. Apparatus, fittings and plans of buildings devoted to scientific research or to technical investigations in biology, therapeutics and hygiene. 2. Appliances, instruments and material employed in the various branches of therapeutics. 3. Working material required in the public service—as in *l'assistance publique* and in rescue from fire or drowning. 4. Plans, apparatus and material required for the reclamation of waste lands and the sanitary regulation of cities. 5. Plans, apparatus and other mechanical aids in the sanitation of cities. 6. Plans, models and materials for sanitary works. 7. Apparatus and furniture for sanitary purposes in dwelling houses and in public offices. 8. Material, apparatus and articles useful in personal hygiene. 9. Plans, models, apparatus and institutions for the hygiene of the working man. 10. Books, atlases, photographs and printed documents of recent publications having reference to the sciences of medicine, biology and hygiene. 11. A special class of exhibits in bacteriology and hydrology. 12. A special class of exhibits in connexion with the Italian Red Cross especially with a view to the competition for the prize instituted in 1892. Diplomas and medals will be awarded to the

best exhibitors by the Minister of the Interior and by the Committee of the 'Esposizione.' For the programmes of the Exhibition and all questions requiring explanation recourse must be had to the President of the Exhibition, the Commendatore Professor Luigi Paghani, whose address *ad hoc* is 'Ministero dell'Interno, Roma.'

VACATION COURSE IN BACTERIOLOGY

WE have been asked to state that, by an error the London Post-Graduate Vacation Course was announced to commence in the Bacteriological Laboratory of King's College on April 11th. The class will commence on April 17th, and will be held every morning from 11 A.M. to 1 P.M., except Saturdays until April 28th. This course has been arranged at the request of the committee of the London Post-graduate Course to suit those practitioners who would be unable to be in London for a longer time than a fortnight.

THE PREVALENCE OF SMALL-POX.

ALTHOUGH during the past fortnight there seems to have been a sensible decline in the total number of cases of small-pox in the country, there have been several fresh centres invaded. In the metropolis, indeed, there have been several cases, and the disease seems to be spreading into localities widely separated from one another, indicating several foci of infection. In Essex cases have occurred—all amongst tramps—in no fewer than ten unions. There have also been cases at Kingston in Surrey, and at Hambledon in Hants. The disease still persists in the Yorkshire towns fresh cases having been received into hospital at Leeds, Bradford, Halifax, Normanton, Bingley and Keighley. The last cases notified at Keighley, a very unvaccinated town, have all been in children, and it is significant in this respect to learn that in Leicester, where the disease is not now spreading, the total number of cases has been 134 with 10 deaths, 8 of the fatal cases being unvaccinated children. Cases have occurred in Westmoreland, at Appleby and Kendal, in Cumberland, at Wyke and Carlisle, and still continue to arise in many of the Lancashire towns, but the most noticeable return is that from South Wales, cases having been notified from Swansea, Unstone, Denbigh, Neath, the Rhondda and Cardiff. At the latter place some difficulty has arisen from lack of special isolation accommodation, and cases of typhus fever have had to be sent out of the hospital in order that small pox cases may be received. The authorities have taken energetic measures to promote vaccination and revaccination. The disease is largely disseminated by the tramp class, and gradually all districts of Great Britain are being invaded by it.

SMALL-POX IN SCOTLAND

THE news this week is both bad and good. In Glasgow there have been no less than twenty-four new cases in the week ending March 11th, as compared with ten and eleven in the two previous weeks. They are, moreover, occurring, some of them, in a rather better class of houses than before—in the houses of respectable artisans and not merely of the very lowest amongst the population. The latter have been, as is pointed out by the convener of the Public Health Committee, to a great extent revaccinated at the public cost, whilst the upper classes have been revaccinated privately in large numbers. But in the class between these there has been very little revaccination so far, and it is this class which small pox is now selecting as its victims. In Kirkcaldy we hear of about half a dozen cases, and in Ayrshire there are at least a dozen, most of them at Lugar. A case has occurred in the town of Ayr, the authorities of which had made no provision for small pox, but in the emergency isolated the patient in a wooden building erected some years ago for cholera. In Govan no less than five persons living in

was very similar to the foregoing, but in it the submaxillary glands were also swollen, and after the lapse of a year all the affected glands had nearly regained their normal condition. In a second case, reported by Mikulicz, there was a uniform and symmetrical enlargement of the lacrymal and of all the maxillary glands, as well as of those of the oral mucous membrane. In a third case, reported by Gordon Norris, there was acute inflammatory swelling of both lacrymal glands, followed in a few days by epidemic parotitis. This may be looked upon as mumps of the lacrymal glands. In addition to these there are cases of a different character, where swelling of the lacrymal glands coexists with enlargement of the lymphatic glands. Three of these cases have been found in literature. Other classes of cases are also referred to by Dr Fuchs (1) Acute or chronic swelling of both lacrymal glands only, (2) acute swelling of the lacrymal and parotid glands in true mumps, (3) chronic swelling of the lacrymal and the various salivary glands from lymphoma or lympho sarcoma, (4) chronic swelling of the lacrymal glands and of the lymphatic glands of the head and neck.

PROSECUTION OF A MEDICAL MAN UNDER THE INFECTIOUS DISEASES NOTIFICATION ACT

AT Worcester, on the 13th inst., Mr G W Till was summoned on a charge of neglecting to notify a case of small pox to the medical officer of health. The prosecution was conducted by Mr T Clark, who stated that the patient, an inmate of a lodging house, was first visited by Mr Till on Dec 23rd, but that he did not notify it until the 26th. After evidence from Dr Crowe, who saw the man in hospital, from the sanitary inspector, from a fellow lodger with the patient, who first notified the case, and from Mr Gostling, acting medical officer of health, it was urged by Mr Matthews in an able speech for the defence that the case was one which Mr Till was justified in regarding at first as chicken pox. Medical witnesses were called to testify to the difficulties in differentiating these two affections in modified cases of small pox, and the Bench unanimously dismissed the case, not allowing costs. It is quite clear that Mr Till did not wilfully withhold notification of the case, the true nature of which he did not at first recognise. It is very desirable that the authorities should endeavour in such cases to discriminate between wilful suppression of the facts and mistaken interpretation of them. It was never intended to prosecute medical men for making a wrong diagnosis, and there is no one who has seen anything of modified small pox who will not admit that there are cases in which, apart from collateral circumstances, an accurate diagnosis is a matter of the greatest doubt and difficulty.

THE "DAILY NURSE"

ONE section of the population which in the emergency of illness is liable to suffer in a peculiar degree from the want of efficient nursing is that commonly known as the lower middle class. Above the status of those who habitually seek attendance at the hospitals, yet at the same time too poor to retain the constant services of a trained nurse, and perhaps isolated in lodgings, there are many persons in this condition of life for whom, when ill, any further aid than the casual services of a friend or a landlady is practically impossible. It is for the relief of such as these that the office of the "daily nurse" was recently evolved from the general nursing system. We are indebted to Miss Catherine Wood, who has taken a leading part in providing the sick with this new and acceptable form of service, for an explanation of her position. It is almost precisely the same as that of the district nurse amongst the poor, except that it entails the payment of moderate fees. The daily nurse visits the patient daily once or oftener, attends to his needs, leaves written instructions, if required, for his friends and a report for the

visiting practitioner. Should her services be required for a longer period, she remains at the bedside during the day or night, returning to the nursing home to sleep. She is thus an inmate of the house of sickness, where space is often very limited, no longer than is absolutely needful for the performance of her duties. In the event of a fatal issue she is likewise available for the last attentions to the dead. The scheme, as above described, has been in operation for about a year, and we understand that it has during this period attained to an encouraging measure of success. It certainly bids fair to satisfy a long felt want, and we fully expect that under judicious management it will prove a great and real boon alike to the sick and to the frequently overworked practitioner whose labours it comes to aid.

LOCAL CONTROL OVER DRAINAGE

IN the issue of the *Builder* for Nov 5th, 1892, appeared a letter from Mr Arthur Baker, F.R.L.B.A., dealing with local control over drainage and sanitary work. Like so many other people who have thought about the subject, Mr Baker takes exception to the present method by which the drainage and sanitation of a district are controlled, and believes that, as now exercised, the whole matter resolves itself into a question of the amount of energy and knowledge possessed by the medical officer of health and local surveyor. We cannot contradict Mr Baker in his contention that the subject upon which he writes is one needing reform, but we do not follow him in his statement that the work of the medical officer of health and surveyor "lies rather in detecting than remedying defects." Surely it is laid down explicitly enough in the list of duties attaching to these offices that both detection and remedy shall be the work of these officials. We quite agree with Mr Baker that the enforcement of a uniform code of model by laws in districts adopting similar methods of sanitation is desirable, and that it would effectually put a stop to the variety of opinions now so freely expressed and carried out as to what should constitute good house drainage. The way by which this goal should be attained requires further deliberation, meanwhile the freer dispersion of a knowledge of hygiene amongst the public, whether by technical education or by the establishment of museums of sanitary appliances, would accelerate the advent of the required reform.

A DELUSIVE ADVERTISEMENT

IT does not often happen that we have to admit any limitation to the efficiency or usefulness of *THE LANCET* as a channel of inter communication, but we have some reason to think that its advertisement columns are not particularly well suited to the requirements of the matrimonial agent, and if any member of that fraternity should be tempted to make, or rather to repeat, the experiment, we would apply to him Mr Punch's advice to those about to marry, and say—don't. So far as an individual matrimonial agent is concerned, he has probably reached that conclusion for himself as the result of a recent experiment which can hardly have proved satisfactory from his point of view. This gentleman caused to be inserted in our columns an advertisement of a medical practice for disposal, which turned out, when answered by one of our readers, to be a bait with which the matrimonial agent was angling for a possible husband in the interest of a young widow described by him in glowing terms. The glowing terms, we hope, do nothing but bare justice to the widow's graces and accomplishments! The description, however, did not impress one of our readers, who has turned over the correspondence to us with indignant comments of his own, and, if the lady be wise, she will probably now adopt some less adventurous plan of bringing her personal recommendations under the notice of possible admirers. With our correspondent's annoyance we heartily sympathise, but we hope that it is

be carried on in French, and it has been agreed that they shall be kept absolutely secret. Dr Schiff of Vienna has made a proposal to the Sanitary Conference for utilising military medical officers and disciplined sanitary corps and the sick transport organisation, together with the military hospitals and infirmaries, supplemented by such temporary shelters and refuges as could be easily built at slight cost by the State in case of the outbreak of an epidemic.

As regards the progress of cholera at the present time it appears that, according to the latest intelligence, the disease continues to prevail to some extent in many of the provinces of Russia and that it has reappeared in Moscow, where cases have occurred in one of the convict prisons of that city. Active preparations are being made, it is stated, throughout Russia, and especially in the province of Moscow, to cope with the returning epidemic.

From Rome we learn that a workman who arrived last week from France at Entraque, near Cuneo had died of what was believed to be cholera from the symptoms during life and the subsequent post-mortem appearances, and that the mother in law of this victim had been since attacked with similar symptoms and had died—presumably from cholera.

CHOLERA IN FRANCE

(FROM OUR SPECIAL CORRESPONDENT)

A VISIT TO BOULOGNE.

Anticipatory Precautions.—A Mayor as a Director.—Infected Fishing Boats.—Comparative Immunity of Streets with Sewers.—The Spread of Cholera in the outlying District.

The municipality of Boulogne-sur-Mer did not wait till cholera had broken out in the neighbouring village of Portel to take the necessary precautions. On Aug. 29th several official committees met and adopted various measures. The sewers were examined, and an investigation was held as to the condition of the different sources of water supply. Applications were made to secure a proper disinfecting stove, and instructions were given to the Chief of the Police with regard to the occasional use of well water in the making of bread and the manufacture of aerated waters. Fortunately for the town of Boulogne, the mayor Dr Aigre, is a distinguished medical practitioner and thoroughly appreciates the importance of good sanitation. He urged the police to apply with the greatest severity all the regulations relating to public health. On Aug. 30th a proclamation was posted throughout the town requesting sailors and fishermen to avoid contact with Ostend, Antwerp and other neighbouring ports where cholera was known to prevail. Orders were given not to expose for sale unripe or over ripe fruit, and to carefully collect every day all death certificates so as to promptly take precautions should any suspicious case occur. Various heaps of manure were removed, sewers disinfected and a number of householders ordered to clean their back yards, their closets &c. Samples of the different sources of drinking water were taken for the purposes of bacteriological analysis. Instructions were issued forbidding the distribution for drinking purposes of any other than the town water supply. A few days later the supply of water from the spring La Prevoyante was suppressed. Various neglected cesspools were hastily emptied and cleaned. All these measures were taken at the end of August and during the first days of September, but at Portel nothing had been done and there cholera began on Sept. 17th and spread with fatal rapidity. This village, inhabited almost exclusively by fishermen, is as I have already explained, three miles to the south west of Boulogne. Four times a day omnibuses go backwards and forwards between the two places. The Portel fishermen come to Boulogne to embark in their boats and their wives come to help to unload the fish, and their daughters to work in the pen manufactures. The entire road from the port through the Capicure side of Boulogne on to Portel, is traversed by persons going from the one place to the other. To reduce this intercourse as much as possible, the Boulogne municipality commenced by suppressing the omnibus service. Then a circular was issued by the Boulogne municipality urging the pen manufacturers not to employ women coming from Portel—at least, for the time being. This un-

doubtedly was a most unjustifiable and somewhat cruel measure to take. Had it been acted upon it certainly would have tended to increase the prevalence of cholera. One of the reasons why cholera spread so rapidly at Portel was the poverty of the population. To stop the women working in the factories would have increased this poverty. It is true that the outbreak of cholera in Boulogne would have caused a general exodus of visitors, and hotel and lodging house keepers would not have let their rooms but the latter are in a better position to support a temporary loss than are the very poor inhabitants of Portel. The lodging-house keepers of Boulogne would not have starved, and, from the sanitary point of view, it was more important not to lessen the financial resources of the much poorer people of Portel.

It was on Sept. 24th that the first death from cholera occurred at Boulogne. The victim was a man of intemperate habits, who lived in the Capicure district and on the road to Portel. As soon as Dr Aigre heard of the case he hastened to the spot. Without waiting for assistance, he at once carried down into the street everything he could find in the dead man's room and made a bonfire with the things justly deeming this to be the most certain means of disinfection. He then proceeded to paste slips of paper over the sides of the window &c. and to prepare the room for fumigation. It was late in the afternoon, and when Dr Aigre had almost completed this work, that a police agent arrived to help him. Dr Aigre was thus able to give the first practical lesson in the art of disinfection and to set a good example as to the necessity of not losing a moment. His energy on this occasion was contagious. It is not every day that one is able to contemplate the picture of the mayor of an important town carrying out dirty bedding, stacks of furniture and other objects from the house of a drunkard who has died from cholera and setting fire to the heap. After that the disinfecting service was promptly and properly organised, but nothing further happened for six days. At the end of that time a fishing boat entered the port with two of the crew on board very ill. The crew numbered nineteen in all, and were far out at sea when some amongst them were seized with violent cramps and vomiting. One of the crew was an inhabitant of Portel. The skipper a powerful man aged thirty-two did what he could to relieve the sufferers, but finding that his efforts were of no avail, he left the fishing grounds and set sail to return to Boulogne. On the way back the skipper himself was seized with cramps, nevertheless, the responsibility that weighed upon him kept him to his post. The sea was rough and the wind contrary. He was drenched from head to foot, but in spite of cramps and diarrhoea he continued in command of the vessel. For two days the crew battled against adverse winds and sickness. When this boat reached Boulogne the authorities acted with extraordinary prudence and energy. The entire crew were marched off to the hospital guarded by gendarmes so that they should not enter any house or communicate with anyone on the way. Two out of the crew were then in an advanced stage of the disease. At the hospital in the course of three days four more fell ill, and out of these six patients I believe four died, including the skipper. As for the other members of the crew they were kept in an observation ward of the hospital by the mere force of persuasion. As they were in perfect health there was no reason why they should be detained, beyond the fear that they should fall ill on reaching home and there spread the epidemic. These excessive precautions however alarmed the fishing population. The crew of the next fishing boat that came into the port of Boulogne with a case of cholera on board refused to go to the observation ward of the hospital. They maintained that they could not afford to be detained some eight days in idleness, wasting their time in the hospital just to see if perchance one or more amongst them should fall ill. As there is no law to compel anyone to undergo this detention, the patient alone was taken to the hospital and the other fishermen went to their homes in the unhealthy overcrowded and badly-drained fishermen's quarter. From that moment and up to the end of December new cases of cholera occurred nearly every day in Boulogne.

Early in October a centre of epidemic became manifest in the two small streets—the Rue de la Redoute and the Rue St. Pol. The map accompanying this article illustrates very well the following description of the progress of cholera in and around Boulogne and Portel. It shows that in these two streets there were altogether thirteen deaths out of twenty-one cases. The first case was that of a man of intemperate habits, living a 22 Rue St. Pol. A

the house from which the first case was taken have been infected. All are in hospital. Cases are reported also from Stranraer, Dundee, Edinburgh and Leith. In the Canongate Hospital there were seventeen cases a few days ago. On the West Highland Railway, where revaccination has been thoroughly carried out, the disease appears to be almost stamped out. On Loch Lomond in Dumbartonshire, indeed, no case has occurred for about a month, and the hospital is undergoing cleansing and disinfecting previously to closure. This is fortunate from a commercial as well as from a sanitary point of view, as with the advance of spring the letting of summer residences begins and the prosperity of the whole locality depends so much on the success of the tourist season that had small pox continued to prevail it would have resulted in great loss alike to railway and steamboat companies and to the hotels and lodging houses on the loch.

DEATH FROM MISADVENTURE

At Diglis, Worcester, an inquest was held by the city coroner (Mr Hulme) relative to the death of Sarah Ann Stead, who had taken an acetonate liniment prescribed for her father in place of her own medicine. The coroner asked Mr Royle, surgeon, if it would not be a good thing that poisons should be put in blue ribbed, specially prepared bottles, to which the witness replied that no doubt it would, but that the law of the land would have to be altered to insist on members of the Friendly Societies Association, of which the witness was surgeon, bringing such bottles.

FOREIGN UNIVERSITY INTELLIGENCE

Innsbruck.—A legacy of 120,000 florins has been left to the University by an eccentric miser, an inhabitant of the city, who has just committed suicide by running himself through the body with a sword.

Tours (Medical School).—M Barnsby, Professor of Natural History, has been appointed Director in place of M Danner, who has been appointed Honorary Director.

DEATHS OF EMINENT FOREIGN MEDICAL MEN

THE deaths of the following distinguished members of the medical profession abroad have been announced.—Dr Damien Leuquin, a much respected Liège practitioner, who, in consideration of valuable services rendered in the time of the cholera epidemic in 1866 as chief medical officer of the Liège division of the Belgian railways and as a member of the Provincial Medical Commission, had been decorated by the Belgian Government and created an Officier de l'Académie by the French Republic. His age was fifty three.—Dr Ferdinand Joseph Belot, hon secretary of the Belgian Provincial Medical Commission and Knight of the Order of Leopold, at the age of eighty four.

A GENERAL MEETING of the British Medical Temperance Association will be held at the London Temperance Hospital, Hampstead road, to-day (Friday). A review of the medical practice in the wards of the London Temperance Hospital will be given by the President, Dr B W Richardson, F R S.

THE Senatus Academicus of the University of Aberdeen has conferred the degree of LL.D on Dr Crum Brown, Professor of Chemistry in the University of Edinburgh, and Sir Frederic Bateman, M D, Senior Physician to the Norfolk and Norwich Hospital.

DR F LAGRANGE has been sent by the French Government to Italy and Germany in order to report upon the various forms of hygienic treatment which are carried out at different sanatoria.

MR HUGH SMITH, F R C S, has been appointed Surgeon to the Hospital Convalescent Home at Parkwood, Swanley, which has been recently erected and is to be opened in May.

Dr JAMES MURPHY has been appointed to the chair of Medical Jurisprudence in the University of Durham College of Medicine at Newcastle-on-Tyne.

OWING to the resignation of Mr Oliver Pemberton, a professorship of surgery in Mason College, Birmingham, is vacant. The latest date for applications is April 14th next.

MR THOMAS BRYANT, President of the Royal College of Surgeons of England, has been elected by the committee a member of the Athenæum Club.

THE London Hospital has received a donation of £3000 from Baron Hirsch for the purpose of installing the electric light in that institution.

DR C H RALFE has been appointed Extern Examiner in Medicine in the University of Durham.

CHOLERA.

INTELLIGENCE has been received from Egypt that a meeting of the Consuls General has been held at Cairo to receive the communication of a provisional understanding between the representatives of the five Great Powers and the Egyptian Foreign Minister respecting the measures to be adopted by the quarantine board in Egypt in accordance with the resolutions of the Venice Sanitary Conference. It is understood that the board is to be reconstituted and the number of its Egyptian members is to be reduced.

The first meeting of the International Sanitary Conference at Dresden took place on the 11th inst. in the building occupied by the Saxon Ministry of Foreign Affairs, in which special preparations had been made for the reception of the delegates. Count Donhoff, the Prussian Minister at the Court of Saxony, who is acting as chief representative of the German Empire, was unanimously elected president. As the French representatives had not arrived at Dresden and the Turkish delegates had also been delayed, the Conference was adjourned and the sitting soon closed. The special correspondent of *The Times* gives the following list of the representatives of the Powers taking part in the Conference.—England is represented by Mr Strachey, Her Majesty's Minister to the Saxon Court, Dr Thorne Thorne, principal medical officer to the Local Government Board, and Mr Farnall, from the Foreign Office. Germany, by Count Donhoff and Professor Koch, aided by Herr von Landmann for Bavaria and Herr von Criegern for Saxony. Austria Hungary, by the Austro-Hungarian Minister, Herr von Hengelmüller, Dr Kuess, Herr von Ebner, from the Ministry of Commerce, Herr Faschomayr, from the Hungarian Home Office, and Herr Vajkay, Chief Engineer of the Hungarian State Railways. Belgium, by M Beco, Secretary of the Ministry of Agriculture and Public Works, and Dr von Ermengen of the University of Ghent. Denmark, by the Danish Minister in Vienna, Herr von Löwenörn, and Dr Lehmann. Spain, by M de Villaurrutia, Minister in Dresden, and Dr San Martín. France, by M Barrère, Minister at Munich, and Professors Proust and Brouardel. Greece, by M Antonopoulos, Chargé d'Affaires at Berlin and Dr Vafiades. Italy, by M Cortopassi, the Italian Minister at Bucharest, and Dr Pagliano. Portugal, by Count Sampaio, Chargé d'Affaires at Berlin. Roumania, by M Ghika, the Minister at Berlin, and Dr Felix, Chief of the Sanitary Board at Bucharest. Russia, by M Jonin and von Wrangell. Servia, by M Pawlowitch, Chargé d'Affaires at Berlin. Norway and Sweden, by Herr von Lagerheim, Minister at Berlin. Switzerland, by Dr Roth and Dr Schmidt, and Holland by M van Ruyssenaers and Dr Ruysch. The proceedings will

carried on in French, and it has been agreed that they shall be kept absolutely secret. Dr Schiff of Vienna has made a proposal to the Sanitary Conference for utilising military medical officers and disciplined sanitary corps and the sick transport organisation, together with the military hospitals and infirmaries, supplemented by such temporary shelters and refuges as could be easily built at slight cost by the State in case of the outbreak of an epidemic.

As regards the progress of cholera at the present time it appears that, according to the latest intelligence, the disease continues to prevail to some extent in many of the provinces of Russia and that it has reappeared in Moscow, where cases have occurred in one of the convict prisons of that city. Active preparations are being made, it is stated, throughout Persia, and especially in the province of Moscow, to cope with the returning epidemic.

From Rome we learn that a workman who arrived last week from France at Entracque, near Cuneo had died of what was believed to be cholera from the symptoms during life and the subsequent post-mortem appearances and that the mother in law of this victim had been since attacked with similar symptoms and had died—presumably from cholera.

CHOLERA IN FRANCE

(FROM OUR SPECIAL CORRESPONDENT.)

A VISIT TO BOULOGNE.

A Hospitalary Peculiarities.—A Mayor as a Disinfectant.—Infected Sleeping Boxes.—Comparative Immunity of Streets with Sewers.—The Spread of Cholera in the outlying Districts.

THE municipality of Boulogne-sur-Mer did not wait till cholera had broken out in the neighbouring village of Portel to take the necessary precautions. On Aug. 29th several official committees met and adopted various measures. The sewers were examined, and an investigation was held as to the condition of the different sources of water supply. Applications were made to secure a proper disinfecting stove, and instructions were given to the Chief of the Police with regard to the occasional use of well water in the making of bread and the manufacture of aerated waters. Fortunately for the town of Boulogne, the mayor, Dr Aigre, is a distinguished medical practitioner and thoroughly appreciates the importance of good sanitation. He urged the police to apply with the greatest severity all the regulations relating to public health. On Aug. 30th a proclamation was posted throughout the town requesting sailors and fishermen to avoid contact with Ostend, Antwerp and other neighbouring ports where cholera was known to prevail. Orders were given not to expose for sale unripe or over-ripe fruit, and to carefully collect every day all death certificates so as to promptly take precautions should any suspicious case occur. Various heaps of manure were removed, sewers disinfected and a number of householders ordered to clean their back yards, their closets &c. Samples of the different sources of drinking water were taken for the purposes of bacteriological analysis. Instructions were issued forbidding the distribution for drinking purposes of any other than the town water supply. A few days later the supply of water from the spring La Prevoyante was suppressed. Various neglected cesspools were hastily emptied and cleaned. All these measures were taken at the end of August and during the first days of September, but at Portel nothing had been done and there cholera began on Sept. 17th and spread with fatal rapidity. This village, inhabited almost exclusively by fishermen, is as I have already explained, three miles to the south-west of Boulogne. Four times a day omnibuses go backwards and forwards between the two places. The Portel fishermen come to Boulogne to embark in their boats, their wives come to help to unload the fish, and their daughters to work in the pen manufacturers. The entire road from the port through the Capricure side of Boulogne on to Portel, is traversed by persons going from the one place to the other. To reduce this intercourse as much as possible, the Boulogne municipality commenced by suppressing the omnibus service. Then a circular was issued by the Boulogne municipality urging the pen manufacturers not to employ women coming from Portel—at least, for the time being. Thus un-

doubtedly was a most unjustifiable and somewhat cruel measure to take. Had it been acted upon, it certainly would have tended to increase the prevalence of cholera. One of the reasons why cholera spread so rapidly at Portel was the poverty of the population. To stop the women working in the factories would have increased this poverty. It is true that the outbreak of cholera in Boulogne would have caused a general exodus of visitors and hotel and lodging house keepers would not have let their rooms, but the latter are in a better position to support a temporary loss than are the very poor inhabitants of Portel. The lodging-house keepers of Boulogne would not have starved, and, from the sanitary point of view, it was more important not to lessen the financial resources of the much poorer people of Portel.

It was on Sept. 24th that the first death from cholera occurred at Boulogne. The victim was a man of intemperate habits who lived in the Capricure district and on the road to Portel. As soon as Dr Aigre heard of the case he hastened to the spot. Without waiting for assistance, he at once carried down into the street everything he could find in the dead man's room and made a bonfire with the things, justly deeming this to be the most certain means of disinfection. He then proceeded to paste slips of paper over the sides of the window &c. and to prepare the room for fumigation. It was late in the afternoon, and when Dr Aigre had almost completed this work, that a police agent arrived to help him. Dr Aigre was thus able to give the first practical lesson in the art of disinfection and to set a good example as to the necessity of not losing a moment. His energy on this occasion was contagious. It is not every day that one is able to contemplate the picture of the mayor of an important town carrying out dirty bedding, sticks of furniture and other objects from the house of a drunkard who has died from cholera and setting fire to the heap. After that the disinfecting service was promptly and properly organised, but nothing further happened for six days. At the end of that time a fishing boat entered the port with two of the crew on board very ill. The crew numbered nineteen in all, and were far out at sea when some amongst them were seized with violent cramps and vomiting. One of the crew was an inhabitant of Portel. The skipper, a powerful man aged thirty-two, did what he could to relieve the sufferers, but finding that his efforts were of no avail, he left the fishing grounds and set sail to return to Boulogne. On the way back the skipper himself was seized with cramps, nevertheless, the responsibility that weighed upon him kept him to his post. The sea was rough and the wind contrary. He was drenched from head to foot, but in spite of cramps and diarrhoea he continued in command of the vessel. For two days the crew battled against adverse winds and sickness. When this boat reached Boulogne the authorities acted with extraordinary prudence and energy. The entire crew were marched off to the hospital guarded by gendarmes, so that they should not enter any house or communicate with anyone on the way. Two out of the crew were then in an advanced stage of the disease. At the hospital in the course of three days four more fell ill, and out of these six patients I believe four died, including the skipper. As for the other members of the crew, they were kept in an observation ward of the hospital by the mere force of persuasion. As they were in perfect health there was no reason why they should be detained, beyond the fear that they should fall ill on reaching home and there spread the epidemic. These excessive precautions, however, alarmed the fishing population. The crew of the next fishing boat that came into the port of Boulogne with a case of cholera on board refused to go to the observation ward of the hospital. They maintained that they could not afford to be detained some eight days in idleness, wasting their time in the hospital just to see if perchance one or more amongst them should fall ill. As there is no law to compel anyone to undergo this detention, the patient alone was taken to the hospital and the other fishermen went to their homes in the unhealthy, overcrowded and badly-drained fishermen's quarter. From that moment and up to the end of December new cases of cholera occurred nearly every day in Boulogne.

Early in October a centre of epidemic became manifest in the two small streets the Rue de la Redoute and the Rue St. Pol. The map accompanying this article illustrates very well the following description of the progress of cholera in and around Boulogne and Portel. It shows that in these two streets there were altogether thirteen deaths out of twenty-one cases. The first case was that of a man of intemperate habits, living at 22 Rue St. Pol. A

the house from which the first case was taken have been infected. All are in hospital. Cases are reported also from Stranraer, Dundee, Edinburgh and Leith. In the Canongate Hospital there were seventeen cases a few days ago. On the West Highland Railway, where revaccination has been thoroughly carried out, the disease appears to be almost stamped out. On Loch Lomond in Dumbartonshire, indeed, no case has occurred for about a month, and the hospital is undergoing cleansing and disinfecting previously to closure. This is fortunate from a commercial as well as from a sanitary point of view, as with the advance of spring the letting of summer residences begins and the prosperity of the whole locality depends so much on the success of the tourist season that had small pox continued to prevail it would have resulted in great loss alike to railway and steamboat companies and to the hotels and lodging houses on the loch.

DEATH FROM MISADVENTURE

At Diglis, Worcester, an inquest was held by the city coroner (Mr Hulme) relative to the death of Sarah Ann Stead, who had taken an acetonite liniment prescribed for her father in place of her own medicine. The coroner asked Mr Royle, surgeon, if it would not be a good thing that poisons should be put in blue ribbed, specially prepared bottles, to which the witness replied that no doubt it would, but that the law of the land would have to be altered to insist on members of the Friendly Societies Association, of which the witness was surgeon, bringing such bottles.

FOREIGN UNIVERSITY INTELLIGENCE

Innsbruck.—A legacy of 120,000 florins has been left to the University by an eccentric miser, an inhabitant of the city, who has just committed suicide by running himself through the body with a sword.

Tours (Medical School).—M Barnsby, Professor of Natural History, has been appointed Director in place of M Druner, who has been appointed Honorary Director.

DEATHS OF EMINENT FOREIGN MEDICAL MEN

THE deaths of the following distinguished members of the medical profession abroad have been announced.—Dr Damien Leurquin, a much respected Liège practitioner, who, in consideration of valuable services rendered in the time of the cholera epidemic in 1866 as chief medical officer of the Liège division of the Belgian railways and as a member of the Provincial Medical Commission, had been decorated by the Belgian Government and created an *Officier de l'Académie* by the French Republic. His age was fifty three.—Dr Ferdinand Joseph Belot, hon. secretary of the Belgian Provincial Medical Commission and Knight of the Order of Leopold, at the age of eighty four.

A GENERAL MEETING of the British Medical Temperance Association will be held at the London Temperance Hospital, Hampstead road, to-day (Friday). A review of the medical practice in the wards of the London Temperance Hospital will be given by the President, Dr B W Richardson, F.R.S.

THE *Senatus Academicus* of the University of Aberdeen has conferred the degree of LL.D on Dr Crum Brown, Professor of Chemistry in the University of Edinburgh, and Sir Frederic Bateman, M.D., Senior Physician to the Norfolk and Norwich Hospital.

DR. F LAGRANGE has been sent by the French Government to Italy and Germany in order to report upon the various forms of hygienic treatment which are carried out at different sanatoria.

MR HUGH SMITH, F.R.C.S., has been appointed Surgeon to the Hospital Convalescent Home at Parkwood, Swanley, which has been recently erected and is to be opened in May.

Dr JAMES MURPHY has been appointed to the chair of Medical Jurisprudence in the University of Durham College of Medicine at Newcastle-on Tyne.

OWING to the resignation of Mr Oliver Pemberton, a professorship of surgery in Mason College, Birmingham, is vacant. The latest date for applications is April 14th next.

MR. THOMAS BRYANT, President of the Royal College of Surgeons of England, has been elected by the committee a member of the Athenæum Club.

THE London Hospital has received a donation of £3000 from Baron Hirsch for the purpose of installing the electric light in that institution.

DR. C H RALFE has been appointed Extern Examiner in Medicine in the University of Durham.

CHOLERA.

INTELLIGENCE has been received from Egypt that a meeting of the Consuls General has been held at Cairo to receive the communication of a provisional understanding between the representatives of the five Great Powers and the Egyptian Foreign Minister respecting the measures to be adopted by the quarantine board in Egypt in accordance with the resolutions of the Venice Sanitary Conference. It is understood that the board is to be reconstituted and the number of its Egyptian members is to be reduced.

The first meeting of the International Sanitary Conference at Dresden took place on the 11th inst. in the building occupied by the Saxon Ministry of Foreign Affairs, in which special preparations had been made for the reception of the delegates. Count Dönhoff, the Prussian Minister at the Court of Saxony, who is acting as chief representative of the German Empire, was unanimously elected president. As the French representatives had not arrived at Dresden and the Turkish delegates had also been delayed, the Conference was adjourned and the sitting soon closed. The special correspondent of *The Times* gives the following list of the representatives of the Powers taking part in the Conference.—England is represented by Mr Strachey, Her Majesty's Minister to the Saxon Court, Dr Thorne Thorne, principal medical officer to the Local Government Board, and Mr Farnall, from the Foreign Office. Germany, by Count Dönhoff and Professor Koch, aided by Herr von Landmann for Bavaria and Herr von Criegern for Saxony. Austria Hungary by the Austro-Hungarian Minister, Herr von Hengelmüller, Dr Kuesy, Herr von Ebner, from the Ministry of Commerce, Herr Faschomoyers from the Hungarian Home Office, and Herr Vajkay, Chief Engineer of the Hungarian State Railways. Belgium, by M Beco, Secretary of the Ministry of Agriculture and Public Works, and Dr von Ermengen, of the University of Ghent. Denmark, by the Danish Minister in Vienna, Herr von Löwenörn, and Dr Lehmann. Spain, by M de Villaurrutia, Minister in Dresden, and Dr San Martín. France, by M Barre, Minister at Munich, and Professors Proust and Brouardel. Greece, by M Antonopoulos, Chargé d'Affaires at Berlin and Dr Vafiades. Italy, by M Curtopassi, the Italian Minister at Bucharest, and Dr Pagliano. Portugal, by Count Selin, Chargé d'Affaires at Berlin. Roumania, by M Ghika, the Minister at Berlin, and Dr Felix, Chief of the Sanitary Board at Bucharest. Russia, by MM Jonin and von Wrangell. Servia, by M Pawlowitch, Chargé d'Affaires at Berlin. Norway and Sweden, by Herr von Lagerheim. Minister at Berlin. Switzerland, by Dr Roth and Dr Schmidt, and Holland by M van Ruyssenaers and Dr Itysch. The proceedings will

woman and a young girl inhabiting the same house also died. Then some relatives living close by at 36, Rue de la Redoute, likewise succumbed to cholera. All these persons were poor, some of them drunkards, and they lived in very insanitary houses. These two streets are on the summit of a steep hill, they are fairly wide and well swept by the wind, they are not so well cared for by the scavengers. I noticed heaps of filth in the Rue St. Pol, which some inhabitants declared had not been removed for fifteen days. No 22 of this street I found to be a very wretched and filthy habitation in spite of all the recent disinfection. There was fecal matter in the entrance passage of the house, and in a small back yard was a broken-down mudden closet, which the occupant of the house declared had not been emptied since cholera occurred. There was no lid to the seat, no pan underneath, and the contents of the midden were exposed to the open air. The staircase was small and dirty, the whole surroundings were grimy and desolate, and, to make matters worse, there were cellar dwellings. Leaking drains pass under the houses and the street gutter receives all manner of dirt and is badly paved, so that the subsoil can be easily contaminated. Nevertheless I have seen many worse slums and there is plenty of fresh air on the crest of the hill where these two streets are situated. It is interesting to note that in the Rue St. Pol are the five 'houses of tolerance' which Boulogne possesses, and that the women of these houses, though living in the very heart of the cholera district, were all absolutely free from sickness. Within a stone's throw is the fishermen's district where most of the other cases of cholera occurred. Thus these women were not only in the worst street, but in the worst neighbourhood so far as cholera was concerned, yet they all escaped. The fact is that, in spite of the wretched, degraded lives they lead, they enjoy material advantages which the general population does not possess. They have each a separate room to sleep in, so there is no overcrowding. They have ample food and no anxiety for the morrow's subsistence. Then they must, of necessity, be kept scrupulously clean. This may explain why they were not affected by the cholera that surrounded them.

The sick were conveyed to the hospital in a special carriage, and, whenever possible, the families were removed for a few days to an observation ward. The houses in the interval were disinfected, the passages and corridors washed, the closets drenched with a solution of sulphate of iron, and as many objects as possible were burnt, whilst the more valuable things were taken to the disinfecting stove. The rooms were disinfected with sulphur fumes where the mercurial spray could not be readily applied. Altogether seventy-eight cases are officially recognised to have occurred in the town of Boulogne, resulting in thirty deaths. The first death occurred on Sept. 24th, and the last on Dec. 31st 1892. It is important to note that from Oct. 17th to Nov. 1st there were only one death and one new case, and it so happened that during all this period it rained, I believe, every day. When the rain ceased new cases and more deaths occurred. Altogether this experience speaks well for Boulogne. Though so close a neighbour to Portel and exposed to infection brought by travellers coming from all parts as well as by the inhabitants of Portel there were but thirty deaths from cholera out of a population of 45,205, so that whilst at only three miles distance the mortality from cholera was equal to 14.26 per 1000 of the population, it only amounted to 0.65 per 1000 at Boulogne. I cannot help thinking that this immense difference is due to the fact that, from the very first, energetic measures were taken to cope with the danger at Boulogne, whilst at Portel the greatest negligence was displayed, but more important, far, than the measures which may be taken on the spur of the moment is the fact that Boulogne has a good water supply and is drained by numerous sewers. At Portel as I have already explained, there are no sewers and the water taken from surface wells is exposed and contaminated from the streets where all the filth is thrown out. There are various water supplies at Boulogne, but the principal supply comes from Tingry, a village situated on a hill at a distance inland of eleven miles. From this source 300 litres per day, per inhabitant, are obtained, and it is brought to Boulogne under pressure in an iron pipe. At Boulogne however there is a reservoir that is not all that could be desired, and orders have been given to have it cleaned, and the walls scraped, flames passed over their surfaces and then tarred. This useful precaution will be taken before the commencement of the next summer season. As the Tingry water has a pressure of only forty-eight metres, it does not

reach the higher portions of the town, and notably the Rue St. Pol and Rue de la Redoute. Together with two-thirds of the fishermen's quarter these streets receive the water of the Ordre. There is also a private company which distributes water in various houses. Then there is a spring known as the Bon Père, which is so near to the surface of the soil as to be looked upon with suspicion. There are two farms close by, and on the fields human manure is thrown, so that it was feared one or more of these supplies would be contaminated. When Boulogne was menaced by cholera some of these smaller supplies of water were suppressed, samples taken, and arrangements made to have them examined. They were all found to be good though the water of the Bon Père spring contained the bacterium coli, the leptothrix &c. Nevertheless, the fact remains that it is the part of Boulogne that does not receive the Tingry water which suffered most from cholera, but there is another very important consideration. There are no sewers in the Rue St. Pol and the Rue de la Redoute, or in the greater part of the fishermen's quarter. Boulogne has more sewers than any of the other French provincial towns that I have visited during the course of my inquiries into the cholera epidemic. More than half the total length of the streets has sewers, including all the important streets. On looking at the map I find that twenty-two cases of cholera occurred in streets where there are sewers and forty-eight in streets where there are no sewers. These figures apply to Boulogne as a whole, but if one takes the Capricure side of the river only the result is the reverse, for here I find nine cases in streets where there are sewers and six where there are none. The sewers seem to have acted beneficially, yet as sewers they are far from perfect and still have their outfalls into the port. Sand, of which a plentiful supply is scattered in the streets, collects in the bottoms of the sewers. It mixes with the heavy deposits and is not readily flushed out. Thus a nuisance arises, and it was a wise precaution to have the sewers specially cleaned when the advent of cholera was feared, indeed, it must be admitted that the administration of the town of Boulogne has displayed a very enlightened spirit and seems bent on dealing with the health question in a broad and scientific manner. Personally I have every reason to be grateful for the efficient and courteous assistance given me in my investigations. No attempt was made at concealment, a map showing where the cases of cholera had occurred and the number of boats that came into port with cholera cases on board was placed at my disposal, whilst the town engineer took the trouble to trace, street by street, the course followed by the sewers and the various water supplies. I regret to be compelled to, at least, defer criticism on the drainage and general sanitary conditions of Boulogne, but I have perhaps said enough to show that the town has gone through a great ordeal with credit and that there is reason to believe that it enjoys a certain degree of immunity from the danger with which it was menaced. The fact that Boulogne has so far escaped from a serious epidemic because its sanitary condition was preferable to that, for instance, of Portel, but that it nevertheless suffered somewhat—namely just in those parts where its sanitary armour was weakest—is surely a clear indication that measures of general sanitary reform, already in part executed, should be pressed forward and promptly terminated.

From Portel the suburb of Boulogne called Outran was contaminated, and 22 cases and 9 deaths occurred there. At St. Etienne, in a district known as "Le Purgatoire," there were 21 cases and 8 deaths. Then there was 1 death at Ique 1 at Coudette of a person who had arrived from St. Etienne, and there were 17 deaths at Halinghen out of a population of only 300 persons. This caused great alarm at Boulogne because Halinghen is near the source of the Boulogne water-supply at Tingry. Fortunately Tingry is on the opposite slope of the hill and there were no cases of cholera on that side. At Neufchatel there were 4 or 5 deaths and at Darne some 20 cases and 4 deaths are reported. These, however, scarcely seem correct figures and doubtless for all these small villages considerable corrections will be ultimately made to the figures actually given. The cholera also spread from the Boulogne *arrondissement* to that of Montreuil and to Etaples. Parenty, Hubert and several other places.

MEDICAL MAGISTRATE—Mr William Bradley, M.R.C.S., has been placed on the Commission of the Peace for the borough of Preston.

MAP OF BOULOGNE AND VICINITY

ILLUSTRATING THE EXTENT AND INTENSITY OF THE RECENT CHOLERA OUTBREAK.

The diagrams outside the pier represent boats. The unshaded sketches are those boats which contain fishermen who have come from Le Portel the shaded boats contain fishermen from other ports. Throughout the map cholera cases are represented by dots or squares. The squares indicate the cases which have proved fatal the dots cases which have recovered. The map illustrates the aggregation of cases at two spots—viz., at Le Portel and at points inhabited chiefly by fishermen residing in Boulogne. Single cases are sparsely distributed over the intervening area.

office on Jan. 11th, 1893, and were received back by the press on Feb. 1st. The report is now ready, but the Government of India are under an engagement to the National Leprosy Association not to publish it here until it can appear simultaneously in England.

'It will thus be evident that the Government of India are not responsible for the delays which have occurred in the several stages of preparing and printing the report, and that under the circumstances under which the Commission was constituted these delays were unavoidable.'

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD

York Rural Sanitary District—Mr T W Thompson has made an exhaustive report to the Local Government Board upon the general sanitary condition of the York rural sanitary district. This district is an extensive one and includes part of each of the three Ridings of Yorkshire. It consists of forty seven contributory places, all of which were inspected by Mr Thompson in the course of his inquiry. The conditions revealed by the report are such as to require the serious and immediate attention of the York rural sanitary authority. We read of cases of excessive overcrowding, water supplies derived from shallow, dry stined, improperly covered and badly situated wells, of sewers imperfectly flushed and ventilated, discharging their crude sewage into rivers and streams, and of midden privies so constructed as not to prevent the percolation of their contents into the soil. The sanitary condition of each of the forty seven villages is fully treated of in the report, but we have not space to notice them in detail. The sanitary authority, apparently as far back as 1876, obtained by laws for part of their district, but, as the report points out, these were framed prior to the issue of the Model By laws, and are thus, to a large extent, obsolete. In the specific recommendations which are found at the end of the report Mr Thompson, in discussing the shallow wells referred to, states that "merely to close wells of this kind and to require the provision of others that are not likely to differ from them in character is often but to put the owner to useless expense without benefitting the tenant." This sentiment we entirely endorse, and it seems to us that it would be well if some steps were taken to bring about a system of registration of well-sinkers, who should be properly educated and qualified for the work they have to perform. In a postscript to the report the sanitary authority are warned that "the prospect of cholera places upon them the imperative duty of availing themselves to the utmost of the months which will elapse before the advent of the warm weather, for the purpose of removing from their district the many unwholesome conditions which have so far been allowed to go unremedied. Should they omit to do this, they will be incurring a responsibility the gravity of which it would be difficult to exaggerate." We hope the report will be widely circulated and read through out the district to which it refers.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Torquay Urban District—Mr Karkeek, who raises some interesting points in his report, in referring to the dangers of cholera which threatened our shores last year observes that inasmuch as there was some doubt as to which ports were to be regarded as infected, he visited every foreign vessel that entered Torquay waters. Among these there were twenty five fishing boats belonging to Isigny and Cherbourg which had been driven into Torquay under stress of weather having made the passage in from thirty six to forty eight hours. The risk to which we are thus exposed is obvious. We notice in this connexion that at the meeting of port sanitary authorities held recently at the Mansion House it was resolved that power should be obtained to require all vessels, including fishing boats which have been in communication with infected or suspected ports to hoist a distinguishing signal on arrival.

No doubt a provision such as this would be of considerable value if it could be relied upon and properly carried out. It seems to us, however, that, with regard to the fishing boat difficulty, it is placing a discretionary power in the hands of a class of men whose ideas of a "suspected" port would differ widely. We believe we are right in saying that there is an order of the Commissioner of Customs in force making it incumbent on any vessel or fishing smack arriving at a British port from a foreign one to hoist her national signal, whether by day or night. It would seem that, if this order be properly insisted upon, we have already in force a precaution likely to be more effectual than that proposed by the conference. It would of course be necessary to further insist that all fishing boats arriving from abroad should stop at the boarding station and be there duly examined by the Customs' officer. In discussing the question of notification, Mr Karkeek relates that the local boards of Torquay, St. Mary Church, Paignton, Totnes and Ashburton united in an attempt to persuade the Newton rural sanitary authority to adopt the Notification Act. These efforts were, however, unavailing. The general and zymotic death rates of the district under consideration were 14.4 and 0.62 per 1000 respectively.

Newton Abbot Rural District—The death rate in this district was 15.81 per 1000 and the zymotic death rate 0.33. Infantile mortality was 84 per 1000 births. Influenza, we are told, "literally raged" during the spring and was primarily accountable for 38 deaths. An epidemic of scarlet fever occurred in May at the village of Broadhempstone and about 50 children were attacked. Notification does not seem to be in force in this district, and Mr Harvey appears not to regard the Act with favour. A number of cases of typhoid fever in Torquay seem to have been traced to a case of the same disease which occurred at a dairy in the Newton rural district. The report does not, however, state what steps were taken to control the distribution of the milk. In treating of the precautions against cholera, Mr Harvey tells us that he endeavoured to persuade the four sanitary authorities—apparently those of Newton, Dawlish and Teignmouth urban, and Newton rural—to combine for the purpose of erecting a cholera hospital. We do not know exactly in what position it was proposed to erect this, but it seems to us that some of the districts in question are too far apart to make such a provision desirable, and this is apparently the view the authorities took of the proposal. It is necessary to bear in mind that the collapse in cholera is, as a rule, so great that those suffering from it are quite unable to withstand the exhaustion produced by a long journey in an ambulance.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS.

In thirty three of the largest English towns 6838 births and 3875 deaths were registered during the week ending March 11th. The annual rate of mortality in these towns, which had increased in the preceding three weeks from 19.2 to 20.8 per 1000, declined again last week to 19.6. In London the rate was 19.1 per 1000, while it averaged 19.9 in the thirty two provincial towns. The lowest rates in these towns were 11.7 in Burnley, 13.9 in Swansea, 14.7 in Blackburn, and 15.0 in Derby, the highest rates were 22.8 in Manchester, 24.1 in Preston, 24.5 in Norwich, 25.3 in Bolton, and 27.6 in Plymouth. The 3875 deaths included 350 which were referred to the principal zymotic diseases, against numbers increasing from 351 to 398 in the preceding five weeks, of these, 96 resulted from measles, 81 from whooping cough, 57 from diphtheria, 41 from scarlet fever, 40 from diarrhoea, 24 from "fever" (principally enteric) and 11 from small pox. No fatal case of any of these diseases occurred last week in Burnley, in the other towns they caused the lowest death rates in Birkenhead, Wolverhampton, West Ham and Birmingham, and the highest rates in Leicester, Plymouth, Leeds, Salford and Bolton. The greatest mortality from measles occurred in Salford, Gateshead, Plymouth, Hull, Newcastle upon Tyne, Huddersfield, Leeds and Bolton, from scarlet fever in Swansea, and from whooping cough in Norwich, Bolton, Salford and Leicester. The mortality from "fever" showed no marked excess in any of the large towns. The 57 deaths from diphtheria included 38 in London, 5 in Cardiff and 4 in Manchester. Six fatal cases of small pox were registered in London, and 1 each in Croydon, Nottingham, Leeds, Sheffield and Sunderland, 203 cases of this

THE LANCET AND THE OATHS ACT, 1888

IN view of efforts that are apparently being made in certain quarters to claim the credit of the abolition of the practice of "kissing the book" we feel bound in justice to ourselves and our readers to give a *resume* of what has appeared in THE LANCET before and since the passing of the Oaths Act in 1888. Starting from the first, we published a short annotation in our issue of Oct. 17th, 1885, entitled "A New Objection to taking Oaths." In this we referred to the action of Mr Stratham, a surgeon then practising in Middlesbrough, who, when summoned to give evidence in a case of drunkenness, objected to swear on the Testament, not for the ordinary reason, but on account of the risk of infection. The objection astounded the magistrates, who, guided by their clerk, ruled that it was not a conscientious objection within the meaning of the Act. The witness at length swore under protest, but, as we remarked at the time, "It must be allowed that there is something in the objection." In the following week (Oct. 24th, 1885) the subject was noticed in the letter of one of our provincial correspondents, who dealt with it at some length under the heading "Medical Witnesses and the Administration of Oaths." He pointed out that, in addition to the risk of infection, kissing the book was open to grave objections, details of which he gave, suggesting the substitution for this of the Scotch mode of taking the oath with uplifted hand, and the repetition by the witness of the words, as being more solemn as well as more cleanly. Subsequently (March 13th, 1886) we published a letter from Dr Harkness of Derby, and in the same volume (May 1st, 8th and 15th) other letters from various correspondents under the heading, "Kissing the Book." Dr Harkness objected to kiss the book in the Divorce Court a few days previously to the appearance of his letter in THE LANCET, giving as his reason the fact that the same Testament had been recently handled and kissed by two notorious prostitutes. After some demur he, at the suggestion of the late Mr Justice Butt, kissed the open page under protest that it still involved handling an unclean thing. He also alluded to what had appeared in THE LANCET. Further suggestions were made by other correspondents and the subject dropped until March 24th, 1888, when we published an annotation on "The Oaths Bill." In this it was suggested that, as it was proposed to allow those who had no religious belief to affirm instead of taking an oath, the opportunity should be taken to permit those who preferred to be sworn with the uplifted hand, as in Scotland, to be so sworn and to dispense in such cases with the kissing of the book. On April 21st and Aug. 25th following we published respectively a letter and an annotation, both of which emphasised this suggestion. On Dec. 24th in the same year (1888) the Oaths Bill received the Queen's consent and nominally became law, though practically it has not become law yet to some magistrates and coroners, metropolitan and provincial. It will now be seen by our readers how very curiously coincident is Section 5, which we repeat: "If any person to whom an oath is administered desires to swear with uplifted hand, in the form and manner in which an oath is usually administered in Scotland, he shall be permitted so to do, and the oath shall be administered to him in such form and manner without further question." In spite of this remarkable coincidence we have never implied that it was owing to what had appeared in THE LANCET that this section was introduced. We have authority for saying that the gentleman (then a member of the House of Commons) who introduced this section had seen the letter and annotations just referred to and intended to have made use of them had there been any discussion, but there was none. The Act with this memorable section was passed for reasons given at great length in an article in *The Solicitors' Journal* of March 4th. It was passed on grounds legal and religious, not medical. Unaware of the passing of the Act and of its fifth section, we returned to the charge in a leading article published in THE LANCET of July 19th 1890, entitled "Oath Taking in Courts of Law." In this we reiterated all that had previously appeared in our columns, and urged the superiority of the Scotch over the English oath. We continued to refer to the subject, as one deserving legislation, on Feb. 7th, 1891 and on Jan. 16th 1892, in annotations headed "Oath Administration." Eventually (THE LANCET, Jan. 23rd, 1892) we received a letter from a correspondent, "L," calling our attention to the Act which had been passed three years before, and quoting

Section 5 in full. After seeing and verifying this we reproduced it in an annotation on Jan. 30th, 1892. On Nov. 26th following, we alluded to the action taken by Dr Gordon Hogg, then recently elected coroner for West Middlesex, to whom will always attach the credit of making this more safe and cleanly form of oath better known to jurors and witnesses. We suggested that Section 5 should be printed and posted on the walls of all courts for the benefit of jurors, witnesses, and other persons likely to be sworn, though we did not add, as it appears we might and ought to have done, for the benefit also of those whose duty it would be to administer the oath. Finally, on Dec. 17th, 1892, we again dealt with the matter in a leading article entitled "Oath Administration: Kissing the Book & the Uplifted Hand." In this we urged medical witnesses to set a good example and to show that they had the courage of their opinions, we also indicated the legal difficulties, which have since been completely solved by the articles in *The Solicitors' Journal* of Feb. 11th of this year and reproduced in THE LANCET of Feb. 18th. On Dec. 24th, 1892, we published a note from a correspondent giving a very practical illustration of the more solemn character of the Scotch oath. During the whole of the period we have traversed, from 1885 to within the last few weeks, we have fought the question single handed. We do not claim, and have never claimed, to have caused the introduction into this country of the Scotch oath, but we do claim to have rescued this section of an Act of Parliament from obscurity and, in the persons of various members of our profession, to have pushed it vigorously into the daylight, notwithstanding the opposition of several legal coroners. In conclusion, we would remind any of our readers who may be called upon to take an oath that they are under no legal obligation whatever to kiss a Bible or Testament, whether it be clean or dirty, unless they wish to do so. If they prefer to swear with uplifted hand they should express a desire to this effect and decline to answer any question.

REPORT OF THE LEPROSY COMMISSION

"Calcutta, Feb. 22nd, 1893.

"SIRS—I have thought it desirable to furnish the press with this communiqué. I shall be much obliged if you also will give it a place in THE LANCET.—Faithfully yours,

"W. R. RICE,

"Surgeon General with the Government of India."

"Adverting to a paragraph which appeared in THE LANCET of Jan. 28th last commenting on the delay in issuing the report of the Leprosy Commission, it should be stated that, although much of the report was written by the Commissioners in India in 1891 before they separated, chapter iii., dealing with the geographical distribution of the disease, its incidence on various castes and sections of the community and the question whether it is on the increase or not, could not be completed until the Commissioners were supplied with certain statistics of the census of 1891. These census statistics were not available before the spring of 1892.

"This delay was enhanced owing to the fact that the three Commissioners nominated from England were obliged, under their agreement with the National Leprosy Association, to leave India within a year of their arrival, whilst much of the report was either not written at all or in an incomplete condition. The difficulty in communication between them and the fourth Commissioner nominated in India was thus intensified. It was not until Aug. 27th 1892, that the final proof of the complete report was received in India by the member of the Commission residing in this country. It was on him that the duty devolved of preparing an index and table of contents. This was done without delay. The maps and diagrams with which the report is illustrated were sent without delay to the Surveyor General's office to be printed, and those required for the larger demy 8vo edition, of which 300 copies have been printed, were not supplied to the press before Dec. 14th, 1892.

"Meanwhile, at the request of the honorary secretary of the National Leprosy Fund, it had been decided to print a cheaper or royal 4to edition for general circulation. The more expensive edition of 300 copies was completed on Jan. 20th, 1893. Then the whole matter had to be overruled for the smaller edition, and the diagrams had also to be recast. These latter were sent to the Surveyor General &

MONTHLY ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON—FEBRUARY, 1893.
(*Specially compiled for THE LANCET*)

Sanitary areas	Estimated population in the middle of 1932.	NOTIFIED CASES OF INFECTIOUS DISEASE.										DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.										Deaths of infants under one year to 1000 births.				
		Small pox	Scarlet fever	Diphtheria +	Typhus fever	Enteric fever	Other common fevers.	Puerperal fever	Erysipelas.	Cholera	Total.	Annual rate per 1000 persons living.	Small pox.	Measles. * Including 60 notified cases of membranous croup

† Including deaths from membranous croup

disease were under treatment in the Metropolitan Asylum Hospitals and 8 in the Highgate Small pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week were 2147, against 2402, 2293, and 2210 on the preceding three Saturdays, 195 new cases were admitted during the week, against 217, 178 and 203 in the previous three weeks. The deaths referred to diseases of the respiratory organs in London, which had been 427 and 385 in the preceding two weeks, further declined to 351 last week, and were 172 below the corrected average. The causes of 69, or 1.8 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Leicester, Oldham, Sunderland, and in eight other smaller towns, the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Liverpool and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20.4 and 23.2 per 1000, in the preceding two weeks, declined again to 22.3 during the week ending March 11th, but exceeded by 2.7 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 11.6 in Greenock and 13.8 in Edinburgh to 25.5 in Glasgow and 28.5 in Dundee. The 627 deaths in these towns included 49 which were referred to measles, 17 to whooping cough, 10 to diarrhoea, 7 to diphtheria, 6 to scarlet fever, 5 to "fever" and 1 to small pox. In all, 95 deaths resulted from these principal zymotic diseases, against 89 and 91 in the preceding two weeks. These 95 deaths were equal to an annual rate of 3.4 per 1000, which exceeded by 1.6 the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 42 and 53 in the preceding two weeks, declined again to 49 last week, of which 19 occurred in Glasgow and 19 in Dundee. The 17 deaths referred to whooping cough exceeded by 2 the number in the previous week, and included 13 in Glasgow. The fatal cases of diphtheria, which had been 10 and 9 in the preceding two weeks, further declined to 7 last week, of which 5 occurred in Glasgow. The 6 deaths from scarlet fever exceeded by 3 the number in the previous week, and included 2 in Glasgow, 2 in Edinburgh and 2 in Leith. Of the 5 fatal cases of "fever" 2 were recorded in Glasgow and 2 in Leith. The deaths referred to diseases of the respiratory organs in these towns, which had been 135 and 171 in the preceding two weeks, declined again last week to 142, and were 12 below the number recorded in the corresponding week of last year. The causes of 39, or more than 6 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin, which had been 27.4 and 27.7 per 1000 in the preceding two weeks, declined again to 25.2 during the week ending March 11th. During the first ten weeks of the current quarter the death rate in the city averaged 28.5 per 1000, the rate for the same period being 22.5 in London and 21.4 in Edinburgh. The 169 deaths in Dublin during the week under notice showed a decline of 17 from the number in the preceding week, and included 6 which were referred to different forms of "fever," 1 to measles, 1 to scarlet fever, 1 to diphtheria, and not one either to small pox or diarrhoea. In all, 10 deaths resulted from these principal zymotic diseases, equal to an annual rate of 1.5 per 1000, the zymotic death rate during the same period being 1.7 in London and 1.0 in Edinburgh. The deaths referred to different forms of "fever," which had been 2 and 6 in the preceding two weeks, were again 6 last week. The fatal case of measles, of scarlet fever, and of diphtheria respectively, were the first recorded for several weeks from these diseases. The 169 deaths registered in Dublin last week included 18 of infants under one year of age and 32 of persons aged upwards of sixty years, the deaths both of infants and of elderly persons showed a marked decline from those recorded in recent weeks. Five inquest cases and 4 deaths from violence were registered, and 67, or more than a third, of the deaths occurred in public institutions. The causes of 12, or more than 7 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING FEBRUARY, 1893.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during the month of February in each of the forty-one sanitary districts of London. With regard to the notified cases of infectious disease in the metropolis during last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases in the accompanying table was equal to 9.7 per 1000 of the population, estimated at 4,305,551 persons in the middle of this year. Owing principally to the decreasing prevalence of scarlet fever in London this rate showed a slight further decline from those recorded in the preceding four months, which had fallen from 17.9 to 9.8 per 1000. Amongst the various sanitary districts the rates last month were considerably below the average in Fulham, St. George Hanover square, Westminster, St. Martin in the Fields, City of London, Rotherhithe, and Woolwich, whilst they showed the largest excess in Holborn, St. Luke, Bethnal Green, Whitechapel, St. George-in-the-East, Limehouse, Poplar, and Battersea. The prevalence of small pox in London showed a further marked increase during February, 158 cases being notified during the month, against numbers rising from 3 to 81 in the preceding five months, of these 158 cases, 22 belonged to Camberwell, 18 to Poplar, 17 to St. George in the East, 10 to Islington, 10 to Whitechapel, 10 to Greenwich, 9 to Marylebone, 7 to Hackney, 7 to Limehouse, 5 to Kensington and 5 to St. Giles sanitary districts. The Metropolitan Asylum Hospitals contained 152 small pox patients at the end of February, against 6, 12, 39, and 60 at the end of the preceding four months, the weekly admissions averaged 38, against 5, 10, and 20 in the preceding three months. The prevalence of scarlet fever in London during February showed a slight further decline from that recorded in recent months, this disease was proportionally most prevalent in Hackney, Strand, Holborn, St. Luke, Whitechapel, Limehouse, Poplar, St. Olave Southwark, and Battersea sanitary districts. The Metropolitan Asylum Hospitals contained 2204 scarlet fever patients at the end of February, against numbers declining from 3843 to 2613 at the end of the preceding four months, the weekly admissions averaged 214, against 429, 363, 254, and 223 in the previous four months. Diphtheria showed increased prevalence during the month under notice, amongst the various sanitary districts this disease showed the highest proportional prevalence in Hammersmith, Chelsea, Hackney, City of London, Bethnal Green, St. George-in-the-East, and Poplar. There were 278 cases of diphtheria under treatment in the Metropolitan Asylum Hospitals at the end of February, against 255, 268 and 268 at the end of the preceding three months, the weekly admissions averaged 58, against 48, 53 and 49 in the previous three months. Enteric fever was proportionally most prevalent during February in Chelsea, St. Luke, Limehouse, Rotherhithe, and Wandsworth sanitary districts. The Metropolitan Asylum Hospitals contained 63 enteric fever patients at the end of February, against numbers declining from 124 to 84 at the end of the preceding four months, the weekly admissions averaged 10, against 12 in each of the preceding two months. Erysipelas showed the highest proportional prevalence during the month under notice in Hammersmith, St. Pancras, Bethnal Green, Limehouse, Battersea, and Wandsworth sanitary districts. Five cases of puerperal fever were notified during February in Hammersmith, 3 in Paddington, and 3 in Camberwell sanitary districts.

The mortality statistics in the accompanying table relate to the deaths of persons actually belonging to the various metropolitan sanitary districts, the deaths occurring in the institutions of London having been distributed amongst the various sanitary districts in which the patients had previously resided. The distribution of these deaths, and especially of those resulting from zymotic diseases, affords the most trustworthy data that can be secured upon which to calculate reliable rates of mortality. During the four weeks ending on Saturday, Feb. 25th, the deaths of 6330 persons belonging to London were registered, equal to an annual rate of 19.2 per 1000, against 19.5 and 26.7 in the preceding two months. The lowest death rates during February in the various sanitary districts were 12.3 in Hampstead, 13.1 in Lewisham (excluding Penze), 14.1 in Wandsworth, 14.4 in Kensington, 15.0 in St. Martin in the Fields, 15.1 in Hammersmith, and 15.6 in Plumstead, in the other sanitary districts the rates ranged upwards to 24.5 in Limehouse, 25.6 in Holborn, 27.4 in St. Olave Southwark, 28.7 in St. Saviour Southwark, 29.1 in

tablet to the memory of the late Surgeon Major R. Keeth, A.M.S., in the Garrison Church, Netley

ARMY COOKING

The new system of army cooking, to which we have frequently referred appears to have excited a good deal of attention not only in this country but abroad, and the present War Minister made the subject one of the features of his speech in introducing his Army Estimates. The French army have sent over to this country some experienced men to inquire into the system of cooking adopted in our army and to inspect the school of cookery. The provision of a sufficient supply of well-cooked food is not only a matter of common requirement and common sense, but it is the first step in practical hygiene. A hungry man is always a discontented man, and occasionally a drunkard. The trite saying that an army marches on its belly is a true one. As regards work, more cannot be got out of a man than is put into him, and a good commissariat is consequently of primary importance—especially in war. It is satisfactory to learn that our soldiers at home are better fed now than they have probably ever been before. The stock pot practically speaking, seems to be the pivot of the new system of cooking at Aldershot and elsewhere.

THE DEPRECIATED RUPEE AND THE CIVIL AND MILITARY SERVICES IN INDIA.

We need not apologise for returning to a subject which has reduced the incomes of several thousands of Europeans engaged in the service of the Government of India by forty per cent. and even threatens to result in the virtual pauperisation of the European services of that country. The Viceroy of India has recognised that the Indian Government cannot ask its public servants to tolerate for an indefinite period the distress borne with so much self command for some time past. Lord Roberts the late Commander in chief in India, and the highest officials there have also recognised the hardship which has been brought about by the large decrease in incomes through the fall in the gold value of the rupee. It is a mistake, moreover to suppose that the lowering of the rate of exchange only affects those who have to send money home for their families, it has innumerable ramifications in other directions. We have been furnished with a copy of a published statement setting forth the evils attributable to the shrinkage of income that has been going on since 1872 and more precipitately since 1886 which, if not soon dealt with, must gravely affect the efficiency of our English administration in India. To quote one, and not by any means the most striking concrete example from the number of those cited in this published statement. It is that of a surgeon-colonel of the Indian Medical Service. This gentleman entered the service in the year 1866, when the rupee stood at 2s. Since the rupee began to decline he calculates his loss of income as aggregating over 25 000 rupees on his home remittances alone. The loss has been so great that, as he declares in a memorial to the Government 'he has barely the pay of a subaltern to live on, though he has done twenty five years service in India, and has risen to the higher ranks.' He has been entitled for some years past to furlough, but it has been impossible for him to avail himself of it." He adds 'that he has nothing to complain of in the way of promotion or appointments—simply a large family to support and educate at home.' It must be remembered that what might be regarded as luxuries in England are necessities in an Indian climate, that all European stores and articles have to be paid for in English money and that the cost of living in India has greatly increased of late years. Amongst those who can afford to avail themselves of the privilege of furlough to England—which is occasionally absolutely necessary for the maintenance of health—many are nowadays compelled to take second-class passages who never did so before.

ST GEORGE'S BARRACKS AS A RECRUIT DEPOT

We are glad to notice that Mr Arnold Forster called the attention of the House of Commons to St. George's Barracks in much the same terms that we employed when animadverting on their condition some time ago, and that, further he indicated a similar remedy to that which we then pointed out. St. George's Barracks are the London centre of recruiting and Mr Arnold Forster said that the place was in a condition which made it necessary that the men who entered the army should leave their self respect behind them, and he trusted that the Secretary of State for War would consider whether something could not be done to have a barrack for recruits in one of the

leading streets of London which was not open to these objections. St. George's Barracks are quite unsuitable quarters for the medical examination of recruits and for recruiting purposes generally. It is satisfactory, therefore, to state that the War Minister admitted that these barracks were undoubtedly not in a creditable condition and that the War Office was negotiating at the present time for a site elsewhere on which to erect a new depot for recruiting. Let us hope that in the interest of the recruiting service it will not be in some dark and gloomy back street but in a light open thoroughfare, and that the new building will be of a character, as regards its external appearance and interior arrangements, to attract young men into the service instead of prejudicing them against it.

Correspondence.

'Audi alteram partem.'

THE SIGNIFICANCE OF ALBUMINURIA.

To the Editors of THE LANCET

SIRS,—IN THE LANCET of March 11th Professor Gardner asks, and goes far to answer the question in the affirmative,

Is there such a thing as 'physiological albuminuria?' In submitting the term some years ago, in THE LANCET and elsewhere, as expressive of a real phenomenon, I dwelt upon the evidence drawn from the observation of the albuminuria of pregnancy. In the old days, when albumen in the urine was looked upon as the decisive symptom of Bright's disease, a disease which implied organic change in the kidney, "physiological albuminuria" was not thought of, but when light was sought elsewhere than in the dead house, when direct clinical observation was appealed to, it came to be recognised that albumen was often found in the urine of persons whose kidneys were healthy. This is "physiological albuminuria." When this occurs it is an indication that under temporary strain or pressure there is a temporary disturbance in the equilibrium of the several functions—that is the temporary incapacity of one or more organs has to be supplemented by other organs until the balance can be restored, when each organ can resume its proper duty and all can work in harmony. Of late years evidence has been accumulating from various sources in illustration of this view. Speaking simply from my own experience, which is but a confirmation of that of many others I adduced the fact, of which I had seen several striking examples when physician to the Seamen's Hospital, of men who, after a sudden immersion in cold water, were affected with albuminuria, and who apparently completely recovered. Such cases surely admit of no other interpretation than that the physiological power was for a time on its trial and then asserted its integrity. But the evidence upon which I have chiefly insisted has been that offered by the luminous experiment of pregnancy. In a healthy young woman becoming pregnant the urine suddenly becomes loaded with albumen. I will not dwell upon the often concomitant nervous symptoms as eclampsia, but will simply call to mind the fact that when the experiment—i.e. the pregnancy—is over, the albumen commonly disappears and the subject returns to perfect health. What is this but "physiological albuminuria"? Pregnancy induces exalted vascular and nervous tension. This tension is too great for the complete response of the kidneys, but reduce the tension by bringing the pregnancy to an end and immediately the kidneys take up their work. Nature always strives to keep within physiological bounds. If she cannot carry on the pregnancy safely she often solves the difficulty by abortion. This is 'conservative abortion,' a lesson to the physician. Sometimes she solves the difficulty by hemorrhage into the intestine, from the uterus, or by epistaxis, or if she cannot find relief by the comparatively safe discharge of blood by a mucous membrane and thus by escape externally there may be internal hemorrhages as in the brain, causing apoplexy. One deeply interesting therapeutical lesson may be drawn from this study. It is to help nature in her physiological difficulty by bleeding. There is no remedy so prompt as this so certain in relieving excessive vascular and nervous tension, in restoring functional equilibrium and reducing the kidney and other organs from the imminent danger of being overtaken to the point of organic change. I do not propo-

St George-in-the-East, 29.9 in St. Luke, and 32.2 in Strand. During the four weeks of February 630 deaths were referred to the principal zymotic diseases in London, of these, 211 resulted from diphtheria, 161 from whooping cough, 94 from scarlet fever, 64 from diarrhoea, 63 from measles, 30 from different forms of "fever" (including 29 from enteric fever, and 1 from an ill defined form of continued fever) and 7 from small pox. These 630 deaths were equal to an annual rate of 1.9 per 1000, against 1.8 2.0, and 2.1 in the preceding three months. Amongst the various sanitary districts the lowest zymotic death rates were recorded in Kensington, Westminster, St Giles, City of London, St. Olave Southwark, and Woolwich, and the highest rates in Strand, Clerkenwell, St George-in-the-East, Limehouse, St. Vincent Southwark, Battersea, and Plumstead. Seven fatal cases of small pox were registered in London during the month under notice, the corrected average number in the corresponding periods of the preceding ten years being 16, of these 7 deaths, one each belonged to Kensington, Fulham, Marylebone, St. Pancras, Hackney, Whitechapel, and Greenwich sanitary districts. The 63 deaths referred to measles were less than half the average, amongst the various sanitary districts this disease showed the highest proportional fatality in Clerkenwell, Shoreditch, Whitechapel and Plumstead. The 94 fatal cases of scarlet fever exceeded by 11 the corrected average, this disease was proportionally most fatal in Marylebone, Strand, St. Luke, and Limehouse sanitary districts. The 211 deaths referred to diphtheria exceeded by as many as 119 the corrected average, amongst the various sanitary districts this disease showed the highest proportional fatality in St. George Hanover square, Hampstead, St. Pancras, St. Luke, Bethnal Green, St. George-in-the-East, Mile End Old Town, Newington and Rotherhithe. The 161 fatal cases of whooping-cough were little more than half the corrected average, this disease was proportionally most fatal in Chelsea, Hackney, Clerkenwell, Battersea, and Greenwich sanitary districts. The 30 deaths referred to different forms of "fever" were 21 below the corrected average, there was no marked excess of "fever" mortality during last month in any of the metropolitan sanitary districts. The 64 fatal cases of diarrhoea slightly exceeded the average. In conclusion, it may be stated that the mortality in London during February from these principal zymotic diseases was as much as 15 per cent. below the average.

Infant mortality in London during the month under notice, measured by the proportion of deaths under one year of age to registered births, was equal to 121 per 1000, and was considerably below the average, the lowest rates of infant mortality were recorded in St. George Hanover square, St. James Westminster, Hampstead, Limehouse, Lewisham, Woolwich, and Plumstead, the highest rates in Fulham, Chelsea, Westminster, Strand, Clerkenwell, St. Luke and Battersea sanitary districts.

THE SERVICES

MOVEMENTS IN THE MEDICAL STAFF

SURGEON LIEUTENANT W. G. BEYTS, is ordered to Woolwich on the 16th inst. Surgeon Major Kenny has arrived in Cyprus. Surgeon Lieutenant Colonel Gallwey, Surgeon Captain Gibbard and Surgeon Lieutenants Alexander and Crawford have embarked on a tour of service in India. Surgeon Captain Robinson has proceeded on duty to Egypt. Surgeon Captain Moore has been transferred from Pontefract to York and Surgeon Lieutenant Lawson to the Station Hospital, Western Heights, Dover. Surgeon Captain Durant has joined at York for duty.

ARMY MEDICAL STAFF

Surgeon Lieutenant Colonel Edwin J. Fairland to be Brigade Surgeon Lieutenant Colonel vice J. R. Greenhill, F.R.C.S. Eng., retired (dated Feb. 16th, 1893).

INDIA AND THE INDIAN MEDICAL SERVICES

The following appointments are announced—Surgeon Lieutenant R. K. Mitter to be Civil Surgeon of the Shwabo District in addition to his military duties. Surgeon Captain H. O. Trevor in Medical Charge of the Station Hospital, Calcutt, to do duty in the Myingyan and Mandalay District. Surgeon Captain C. A. Young doing duty in the Belgaum and Bengalore District, to the Medical Charge of the Station Hospital Calcutt. Surgeon Captain G. C. Hall to act as District Sur-

geon, Rajahmundry, during the absence of Surgeon Major H. St. C. Carruthers, on leave. Brigade-Surgeon Lieutenant Colonel S. B. Hunt to be Surgeon, Fourth District, Madras without prejudice to his present acting appointment. Brigade Surgeon Lieutenant-Colonel H. James Hazlett to be Surgeon, Third District, Madras. Surgeon Major C. M. Thompson, M.B., to act as Surgeon, Fourth District, Madras during the employment of Brigade Surgeon Lieutenant Colonel S. B. Hunt, on other duty. The services of Brigade-Surgeon Lieutenant-Colonel S. O. B. Banks, F.R.C.S., are temporarily placed at the disposal of Government in the Military Department. Surgeon Major H. W. B. Boyd, F.R.C.S., is appointed to act as Presidency Surgeon, Second District, and Marine Surgeon, in addition to his own duties, during the absence of Brigade-Surgeon Lieutenant Colonel S. O. B. Banks. Dr. J. L. Hendley is appointed to be Honorary Surgeon of the Decca Volunteer Rifle Corps vice Surgeon Major Cobb. The services of Surgeon Major W. G. King, I.M.S., are placed at the disposal of the Public Department. Surgeon Colonel P. S. Turnbull, M.D., I.M.S., is promoted to be Surgeon Major General, with effect from Feb. 26th, 1893, vice Surgeon Major General J. Pinkerton, M.D., retired. Dr. Coates, Civil Surgeon at Simla, has been selected for the Civil Surgeoncy at Lahore, when Dr. Center retires from the service in April. Dr. Cunningham from Mooltan will succeed Dr. Coates. Leave has been granted to Surgeon Captain E. O. Wright, A.M.S., to England, for seven months, and to Surgeon Major P. Warliker, I.M.S., in Medical Charge, 1st Regiment Madras Infantry (Pioneers), for six months. Surgeon Colonel A. H. Hilson, M.D., Inspector General of Civil Hospitals, Bengal, has been granted leave for eight months. Surgeon Major J. French Mullen Civil Surgeon of Rayshahi, has been allowed furlough for one year and fifteen days.

NAVAL MEDICAL SERVICE

The following appointments are announced—Surgeon Samuel J. Oddie, M.B., to the *Starling* (dated March 11th, 1893). Surgeon and Agent Mr. Thomas Macdonald, M.B., at Ullapool (dated March 9th, 1893).

MILITIA.

4th Battalion, the Border Regiment. Thomas Ricketts Morse, Esq. late Surgeon Captain, Army Medical Staff, to be Captain (dated March 15th, 1893).

YEOMANRY CAVALRY

Yorkshire Dragoons. Surgeon Captain F. R. Fairbank, M.D., resigns his commission (dated March 11th, 1893).

VOLUNTEER CORPS.

Rifle 1st Volunteer Battalion, the Cheshire Regiment. Surgeon Lieutenant J. R. McNeill, M.D., resigns his commission (dated March 11th, 1893)—1st (Brecknockshire) Volunteer Battalion, the South Wales Borderers. Andrew Whyte, M.D., to be Surgeon Lieutenant (dated March 11th, 1893).

OPENING OF THE SUMMER SESSION, ARMY MEDICAL SCHOOL, NETLEY

Surgeon Lieutenant-Colonel Fairland, Assistant Professor of Medicine, has been selected to give the introductory lecture on the opening of the Summer Session at the Army Medical School, Royal Victoria Hospital, Netley, on Monday, April 3rd.

THE DIPLOMA IN PUBLIC HEALTH AND THE ARMY MEDICAL SCHOOL, NETLEY

The syndicate appointed to superintend the Examinations in State Medicine at Cambridge has acceded to the application for the recognition of the course of instruction in Practical Hygiene in the Army Medical School, Netley, as qualifying for the Examination for the Diploma in Public Health in the University. This is a point of the greatest interest to the officers of the Medical Staff and Indian Medical Service, as it renders increased facility to the members of the Services when presenting themselves for the examinations for this diploma. Up to the present time comparatively few officers have been able to obtain this qualification (one of especial value to military medical officers who are constantly engaged with questions of sanitation and the health of our forces) in consequence of a certificate having been required of attendance at a six months' course of Practical Hygiene at a recognised school.

THE LATE SURGEON MAJOR KEITH

Permission has been given for the erection of a memorial

to the memory of the late Surgeon-Major R. Keesh, A.M.S., in the Garrison Church. New York.

ARMY COOKING

The new system of army cooking to which we have frequently referred appears to have excited a good deal of attention not only in this country but abroad, and the present War Minister made the subject one of the features of his speech in introducing his Army Estimates. The French army has sent over to this country some experienced men to inquire into the system of cooking adopted in our army and to inspect the school of cookery. The provision of a sufficient supply of well-cooked food is not only a matter of common requirement and common sense, but it is the first step in practical hygiene. A hungry man is always a discontented man, and occasionally a drunkard. The true saying that an army marches on its belly is a true one. As regards work, more cannot be got out of a man than is put into him, and a good commissariat is consequently of primary importance—especially in war. It is satisfactory to learn that our soldiers at home are better fed now than they have probably ever been before. The stock pot, practically speaking, seems to be the pivot of the new system of cooking at Aldershot and elsewhere.

THE DEPRECIATED RUPEE AND THE CIVIL AND MILITARY SERVICES IN INDIA.

We need not apologise for returning to a subject which has reduced the incomes of several thousands of Europeans engaged in the service of the Government of India by forty per cent. and even threatens to result in the virtual pauperisation of the European services of that country. The Viceroy of India has recognised that the Indian Government cannot ask its public servants to "obey for an indefinite period the distress borne with so much self-command for some time past. Lord Roberts, the late Commander in Chief in India, and the higher officials there have also recognised the hardship which has been brought about by the large decrease in incomes through the fall in the gold value of the rupee. It is a mistake, moreover, to suppose that the lowering of the rate of exchange can affect those who have to send money home for their families. It has innumerable ramifications in other directions. We have been furnished with a copy of a published statement setting forth the evils attributable to the depreciation of income tax, which has been going on since 1872 and more precipitately since 1893, which, if not soon dealt with, must gravely affect the efficiency of our English administration in India. To quote one, and not by any means the most striking concrete example from the number of those cited in this published statement. It is that of a super-colonel of the Indian Medical Service. This gentleman entered the service in the year 1853, when the rupee stood at 2s. Since the rupee began to devalue he calculates his loss of income as aggregating over 25,000 rupees on his home remittances alone. The loss has been so great that, as he declares in a memorial to the Government, he has been reduced to the pay of a subaltern to live on, though he has done twenty-five years' service in India, and has risen to the higher ranks. He has been entitled for some years past to furlough, but "it has been impossible for him to avail himself of it." He adds "that he has nothing to complain of in the way of promotion or appointments—except a large family to support and educate at home. It must be remembered that what might be regarded as luxuries in England are necessities in an Indian climate, that all European stores and articles have to be paid for in English money, and that the cost of living in India has greatly increased of late years. Amongst those who can afford to avail themselves of the privilege of furlough to England—which is occasionally also well-necessary for the maintenance of health—must be novices compelled to take second-class passages who never did so before."

ST GEORGE'S BARRACKS AS A RECRUIT DEPOT

We are glad to notice that Mr. Arnold Forster called the attention of the House of Commons to St. George's Barracks in much the same terms that we employed when animadverting on their condition some time ago, and that, further, he indicated a similar remedy to that which we then pointed out. St. George's Barracks are the London centre of recruiting, and Mr. Arnold Forster said that the place was in a condition which made it necessary that the men who entered the army should leave their self-respect behind them, and he trusted that the Secretary of State for War would consider whether something could not be done to have a barrack for recruits in one of the

leading streets of London which was not open to these objections. St. George's Barracks are quite unsuitable quarters for the medical examination of recruits and for recruiting purposes generally. It is satisfactory, therefore, to state that the War Minister admitted that these barracks were undoubtedly not in a creditable condition and that the War Office was negotiating at the present time for a site elsewhere on which to erect a new depot for recruiting. Let us hope that in the interest of the recruiting service it will not be in some dark and gloomy back street, but in a light open thoroughfare, and that the new building will be of a character as regards its external appearance and interior arrangements, to attract young men into the service instead of precluding them against it.

Correspondence.

"Audi alteram partem."

THE SIGNIFICANCE OF ALBUMINURIA.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of March 11th Professor Gardner asks and goes far to answer the question in the affirmative.

Is there such a thing as physiological albuminuria? In submitting the term some years ago, in THE LANCET and elsewhere, as expressive of a real phenomenon, I dwelt upon the evidence drawn from the observation of the albuminuria of pregnancy. In the old days, when albumen in the urine was looked upon as the decisive symptom of Bright's disease, a disease which implied organic change in the kidney, physiological albuminuria was not thought of, but when light was sought elsewhere than in the dead house, when direct clinical observation was appealed to, it came to be recognised that albumen was often found in the urine of persons whose kidneys were healthy. This is 'physiological albuminuria.' When this occurs it is an indication that under temporary strain or pressure there is a temporary disturbance in the equilibrium of the several functions—that is the temporary incapacity of one or more organs has to be supplemented by other organs until the balance can be restored, when each organ can resume its proper duty and all can work in harmony. Of late years evidence has been accumulating from various sources in illustration of this view. Speaking simply from my own experience, which is but a confirmation of that of many others, I adduced the fact of which I had seen several striking examples when physician to the Seamen's Hospital, of men who after a sudden immersion in cold water, were affected with albuminuria, and who apparently completely recovered. Such cases surely admit of no other interpretation than that the physiological power was for a time on its trial and then asserted its integrity. But the evidence upon which I have chiefly insisted has been that offered by the luminous experiment of pregnancy. In a healthy young woman becoming pregnant the urine suddenly becomes loaded with albumen. I will not dwell upon the often concomitant nervous symptoms as eclampsia, but will simply call to mind the fact that when the experiment—i.e. the pregnancy—is over the albumen commonly disappears and the subject returns to perfect health. What is this but physiological albuminuria? Pregnancy induces exalted vascular and nervous tension. This tension is too great for the complete response of the kidneys, but reduce the tension by bringing the pregnancy to an end and immediately the kidneys take up their work. Nature always strives to keep within physiological bounds. If she cannot carry on the pregnancy safely she often solves the difficulty by abortion. This is 'conservative abortion,' a lesson to the physician. Sometimes she solves the difficulty by hæmorrhage into the intra-uterine, from the uterus, or by ectasis, or if she cannot find relief by the comparatively safe discharge of blood by a mucous membrane and thus by escape externally, there may be internal hæmorrhages, as in the brain, causing apoplexy. One deeply interesting therapeutic lesson may be drawn from this story. It is to help nature in her physiological difficulty by bleeding. There is no remedy so prompt as this so certain in relieving excessive vascular and nervous tension, in restoring functional equilibrium and rescuing the kidney and other organs from the imminent danger of being overtaxed to the point of organic change. I do not propose

that venesection should take the place of the induction of labour, which is in most cases the proper course to adopt, but to insist upon it as a valuable resource in particular cases. It will rarely be advisable in "chronic albuminuria", it may occasionally be useful in Pavy's "cyclic albuminuria" and still more often in those cases of sudden albuminuria, such as the result of exposure to cold, or what may be called accidental causes. The important point is never to allow albuminuria to persist. Cut it short, if possible, whilst still "physiological," and so lessen the tendency to lapse into the pathological form.

I have so often dwelt upon the importance of studying the problems of pathology by the light of the physiological experiments presented by menstruation and pregnancy that I fear to become tiresome, but, as this source of knowledge is still particularly neglected by those who make a special study of kidney disease, I must plead justification.

I am, Sirs, yours faithfully,

March, 1893

ROBERT BARNES, M D

CHLOROFORM ANÆSTHESIA.

To the Editors of THE LANCET

SIRS,—The conclusion arrived at by the Hyderabad Commission on Anæsthetics that chloroform kills by interference with respiration is, no doubt, correct in the large majority of fatalities with this drug. But when the Commission goes on to lay it down as a law in the administration of chloroform that the pulse need not be noted that indeed noting it is actually harmful because it takes the anæsthetist's attention off the only thing worth watching, the respiration, it goes too far. A large number of cases have of course been published in which chloroform, properly administered, has caused death by paralysing the heart before it interfered with the process of respiration, but the teaching of the Commission is so positive, and, as many surgeons and anæsthetists think, so dangerous, that all cases in which the heart was first affected should be made known. Two such cases occurred at the Royal Victoria Hospital, Netley, lately. A skilled anæsthetist gave the chloroform from a Krohne's inhaler, than which there is no better apparatus for the purpose, and no struggling took place in either case. One was the case of a child aged three years, on whom the operation of needling was being performed for a congenital cataract, but as the operation was completed the boy's face suddenly became pale, and the pulse was found to be imperceptible at the wrist and in the neck. At this time no cessation of the movements of the chest and abdominal walls took place, and air was heard to pass in and out of the lungs freely. Under the use of the interrupted current, friction and ether subcutaneously, the attack of syncope passed off. The second case was that of a man on whom the "radical cure" was being performed for an inguinal hernia. The patient took the chloroform perfectly until the sac of the hernia was twisted. When this was done the man's face immediately blanched and the pulse became imperceptible, whilst the movements of respiration continued vigorous and effective. Ether was injected, the head lowered, sponges wrung out of very hot water were applied over the heart, and electricity to the neck. In about five minutes the pulse was again to be felt and the man recovered. Had the rules laid down by the Hyderabad Commission for the administration of chloroform been carried out in these two cases, had the indications afforded by observation of the pulse been disregarded and the condition of the respiration alone noted, the chances are that the deaths of these patients would have had to be added to the already too long list of "deaths under chloroform." But, luckily, the cessation of the pulse was one of the danger signals which was being looked for, and on its appearance steps were immediately taken to prevent the catastrophe of which it was the first sign.

When the dangerous symptoms arose in these cases the attention of those present was called to the sequence of events—that the pulse had quite ceased to be felt, whilst not only did the movements of respiration continue, but that they were effective in moving the air freely in and out of the lungs. I lay stress on this latter point because it does now and then happen during anæsthesia that the respiratory movements are vigorous, whilst no air can enter the chest on account of closure of the glottis. The twisting of a portion of the peritoneum may have had some effect in producing the syncope in the second case, nevertheless, you may con-

sider this note worth publication as *apropos* to the most points in chloroform anæsthesia.

I am, Sirs, yours truly,

W. A. STEVENSON,

March, 1893 Professor of Surgery, Army Medical School, Netley

THE PRACTICAL WORKINGS OF THE "LEICESTER SYSTEM"

To the Editors of THE LANCET

SIRS,—I think the following illustration of the way this much vaunted "system" is carried out will interest and astonish you. On Monday morning (March 6th) I found two men suffering from small pox lying in one bed in a double bedded room in a thickly populated part of the town. As there were six children and a man lodger (as well as the two patients), besides the father and mother, in the house, I thought these cases ought to be removed to the fever house without delay and I made a special journey to the health office, thereby ensuring the removal of these patients twenty-four hours sooner than they would have been if I had followed the usual course of sending the notification by post. Having placed the authorities on such advantageous terms I determined to observe the application of the prompt and vigorous "isolation method" which Leicester employs to prevent the dissemination of small pox, so thirty-six hours after the removal of the patients I called at the house and found that the authorities were burning sulphur there. The children were playing in the back yard, which was separated from other back yards by a 4 ft. wall, and the husband (who was a servant of the corporation) was told that he must not go to work, but that his wages would be paid and that he was to keep the children from mixing with others, he would, however, be allowed to take them after dark (sic) for a run in the Victoria Park (Leicester's right lung and the evening promenade of the people), and at night between 7 and 8 o'clock the husband and the four boys could take their prescribed walk. During some part of the day they are allowed to go and work on an allotment the husband has about a mile from the house, there are forty or fifty allotments adjoining his, and there is nothing to prevent the other holders and their children from going to work there. Last Saturday the husband was told that he could go to the town hall to draw his allowance, which he did, receiving a sovereign in lieu of wages whilst he was in "quarantine." Now comes the most remarkable incident of this "isolation system." The man who slept in the other bed in this double-bedded room where the two small pox patients lay was allowed to go to work as usual and has done so ever since. He works at the Midland Railway tunnel widening, where over 200 men are employed. I am simply stating facts. I will make no comments, but in conclusion let me say that a greater mass of incongruities and a greater bundle of inconsistencies than this "Leicester system" never emanated out of Bedlam.

I am, Sirs, yours truly,

JOHN T H DAVIES, M D Brux

Leicester, March 14th, 1893.

"OBSERVATIONS ON THE PREVALENCE OF TYPHOID FEVER AMONGST BRITISH SOLDIERS IN GARRISON IN EGYPT"

To the Editors of THE LANCET

SIRS,—I would feel obliged if you would give me space to make a few comments on Dr Mackie's article under the above heading which appeared in THE LANCET of Jan. 28th.

1 Dr Mackie's comparison between the relative prevalence of enteric fever amongst the British soldiers and the general population of Alexandria does not appear to me to be a just one. The population of Alexandria consists generally of Arabs, Levantines and other natives of the Mediterranean littoral, all of whom are born and bred in an atmosphere of insanitation and have been exposed to the contagium of enteric fever from infancy, at which age I believe it probable most of them pass through the disease, those that remain being the survival of the fittest. Such a view will account for the enormous infantile mortality in Alexandria and the apparent immunity of indigenous adults from enteric fever. For such a purpose the British soldier must be compared with persons of his own nationality and age. Roughly speaking, one soldier in ten contracted enteric fever during the

per year. Will Dr Mackie say that the disease does not prevail to at least this extent amongst the young British officers, the wives of officers, bank or mercantile clerks or English mail-erants? In my experience, in the latter class it prevails to about double the amount.

2 With regard to Dr Mackie's theory that the disease is communicable by clothes &c.—i.e., infectious. Surely if this were so we could find the disease running a similar course to other infectious or contagious diseases. But is this so? Is there a greater prevalence in one company than in another, or in one barrack-room than in another? The following list gives the number of admissions by companies 1st Devon Regiment, 1892, and the number admitted from each barrack-room. A Company = 14 B = 9, C = 12, D = 7, E = 8, F = 6, G = 8, H = 7. No 1 barrack room = 4, No 2 = 3, No 4 = 1, No 6 = 2, No 7 = 2, No 8 = 2, No 13 = 1, No 14 = 5, No 15 = 1, No 16 = 1, No 17 = 2, No 18 = 1, No 19 = 1. Every room occupied except No. 5, a very small room, supplied one or more cases of enteric fever. All the remaining cases were admitted from camp or elsewhere. Again, if one soldier buys an article of clothing which belonged to a deceased comrade, and he in his turn contracted the fever, would it not be very soon noticed by the men themselves? But no such feeling exists. I regret that the regiment (1st Devonshire) in which the epidemic occurred last year has now left this country, so that I am unable to ascertain by individual inquiry to what extent purchases of deceased men's clothing were made by those who contracted the disease. I have written to India for this information and will communicate it to you on receipt.

3 With regard to the distribution of infection by barracks and bedding the very facts adduced by Dr Mackie seem to disprove his theory. The 1st Devon Regiment, a very young corps, straight from England, marched into Ras-el-Tin Barracks on the very day that they were vacated by the 2nd Suffolk, Feb. 11th, 1891. The latter regiment had just passed through a very severe epidemic of enteric fever, yet for the whole of that year the Devons enjoyed excellent health. There were no cases of enteric fever at all for over six months and only a few sporadic cases and no deaths towards the close of the year. The epidemic in this regiment did not occur until eighteen months after the barracks were vacated by the Suffolks. In the same connexion Dr Mackie states "The tenacity with which the disease clings to a regiment is shown" by the disease pursuing them when turned into camp, the germ having been transported with them from the barracks." A more reasonable explanation seems to be that the water supply in the camp and in the barracks is identical. The water supply is, to my mind, so obvious a cause for the disease that any hypothetical theory, such as personal infection, appears to be uncalled for. The Mahmoudieh canal is the sole water supply of Alexandria. It is some forty miles long and is a great highway of traffic, with a large floating population and inhabitants living on its banks whose habits are filthy in the extreme. It is a pretty frequent receptacle for carcases, varying in size from a camel to a cat, and is in fact little better than a sewer. If a better cause be needed, it is not far to seek. The odours of Alexandria are almost unrivalled and the system of sewerage, where it exists is most defective.

4 With regard to Dr Mackie's observations on simple continued fever, I am far from denying that a certain number of cases of this disease may be mild enteric fever although the greatest pains are taken in the diagnosis of each case but the large number of cases quoted by him is very misleading. In a military hospital a name, according to nomenclature must be given to each disease. Nothing is more common than for a man to report sick with a headache and slight rise of temperature, perhaps one or two degrees. He is necessarily admitted to hospital, is discharged again in a few days and figures in the return as S C Fever. In civil life he would probably not be seen by a doctor at all, or at the most once or twice. Who that lives abroad is not familiar with the term, a touch of fever? Yet, if Dr Mackie's suggestions were to be carried out all such cases would have to be treated as though they were dealing with a case of plague. I might have proposed a theory which presents itself to me and which bears a much wider aspect. This and other insular countries are at present in much the same condition as England was some fifty years ago. At that time enteric fever was unknown or not recognised. As attention began to be paid to sanitary matters the disease made its appearance. Why was this? Was it a new disease?

What if it always existed? but that with bad sanitation it was a disease of infancy and as such escaped notice. We know how difficult it is to diagnose this disease in early life—without a thermometer, almost impossible. As sanitation improved the infants escaped the disease, but were then liable to contract it as adults whenever they became exposed to the contagium. If this theory be correct it would follow as an axiom that in a locality with bad sanitation there would be a high infant mortality and a low adult mortality of the indigenous adult inhabitants from enteric fever, whilst visitors from more favoured places would be very liable to contract the disease, exactly as we find in this country and in India, and further, that the greater the protection afforded to infants the less the immunity in later life.

I am, Sirs, yours faithfully,

W L CHESTER, M.B.,
Surgeon Major A.M.S.

Alexandria Feb 15th 1893.

THE BRITISH INSTITUTE OF PUBLIC HEALTH.

EXAMINATION OF SANITARY INSPECTORS.

To the Editors of THE LANCET

SIRS.—I fear your article in THE LANCET of March 11th is calculated to give an erroneous impression as to the objects of this Institute in connexion with the training and examination of sanitary inspectors. I shall therefore be obliged if you will allow me to say a few words on the subject. The Public Health (London) Act, 1891, Section 103 (2) (d), enacts that after the year 1894 practically no person shall be appointed within the metropolitan area to the office of sanitary inspector who does not possess a certificate of competency approved by the Local Government Board. As one of the bodies having powers to examine sanitary inspectors for this purpose, we in September last approached the Local Government Board on the subject and in our communication represented that in the public interest it was desirable that one examining board, on the lines of that formed by the Royal College of Physicians of London and the Royal College of Surgeons of England, should be formed for the examination of sanitary inspectors in England, the certificate emanating from which should be subject to the approval of the Local Government Board. In consequence of this communication the Local Government Board wrote to the Sanitary Institute on Dec. 21st, 1892, a letter from which the following is an extract "In the opinion of the Board it is undesirable that there should be a number of bodies independently holding examinations and granting certificates for the purposes above referred to. It seems to the Board that the most satisfactory course would be that some system of joint examination should be instituted by the Sanitary Institute and the British Institute of Public Health." To that letter I understand no reply has yet been received. As one fairly intimately acquainted with the whole bearings of this question, I am at a loss to understand on what authority you say, "There is no reason for believing that the Sanitary Institute desires to retain a monopoly of the examination or to prevent the constitution of some other body to undertake this important work." I only hope your surmise is correct. So far as the Mansion House meeting is concerned, in addition to the invitations which were sent, it was advertised in *The Times* and, I think, in six other daily papers and it was called neither for the purpose of disparaging the Sanitary Institute nor for the advantage of any other body, indeed, with the exception of Dr Littlejohn, our president-elect, none of this Institute's more prominent members took any part in the proceedings. The main object of the meeting was to strengthen the hands of the Local Government Board in carrying out the idea—initiated by this Institute and, I am glad to see, approved by yourselves—that there should be one conjoint examining board for England for the purpose of examining sanitary inspectors. The meeting was most successful and representative, delegates attending from many parts of England and Wales, Scotland and Ireland and I cannot doubt that the following resolution, which was unanimously passed, will have its proper weight with the Government "That this conference of delegated representatives of the sanitary authorities of Great Britain and Ireland held at the Mansion House, London, Feb. 18th, 1893, having considered the provision of the Public Health (London) Act 1891, requiring that every sanitary inspector appointed under the Act, except in the case of those specified

that venesection should take the place of the induction of labour, which is in most cases the proper course to adopt, but to insist upon it as a valuable resource in particular cases. It will rarely be advisable in "chronic albuminuria", it may occasionally be useful in Pavy's "cyclic albuminuria" and still more often in those cases of sudden albuminuria, such as the result of exposure to cold, or what may be called accidental causes. The important point is never to allow albuminuria to persist. Cut it short, if possible, whilst still "physiological," and so lessen the tendency to lapse into the pathological form.

I have so often dwelt upon the importance of studying the problems of pathology by the light of the physiological experiments presented by menstruation and pregnancy that I fear to become tiresome, but, as this source of knowledge is still particularly neglected by those who make a special study of kidney disease, I must plead justification.

CHLOROFORM ANÆSTHESIA

To the Editors of THE LANCET

SIRS,—The conclusion arrived at by the Hyderabad Commission on Anæsthetics that chloroform kills by interference with respiration is, no doubt, correct in the large majority of fatalities with this drug. But when the Commission goes on to lay it down as a law in the administration of chloroform that the pulse need not be noted that indeed noting it is actually harmful, because it takes the anæsthetist's attention off the only thing worth watching, the respiration, it goes too far. A large number of cases have of course been published in which chloroform, properly administered, has caused death by paralysing the heart before it interfered with the process of respiration, but the teaching of the Commission is so positive, and, as many surgeons and anæsthetists think, so dangerous, that all cases in which the heart was first affected should be made known. Two such cases occurred at the Royal Victoria Hospital, Netley, lately. A skilled anæsthetist gave the chloroform from a Krohne's inhaler, than which there is no better apparatus for the purpose, and no struggling took place in either case. One was the case of a child aged three years, on whom the operation of needling was being performed for a congenital cataract, but as the operation was completed the boy's face suddenly became pale, and the pulse was found to be imperceptible at the wrist and in the neck. At this time no cessation of the movements of the chest and abdominal walls took place, and air was heard to pass in and out of the lungs freely. Under the use of the interrupted current, friction and ether subcutaneously, the attack of syncope passed off. The second case was that of a man on whom the "radical cure" was being performed for an inguinal hernia. The patient took the chloroform perfectly until the sac of the hernia was twisted. When this was done the man's face immediately blanched and the pulse became imperceptible, whilst the movements of respiration continued vigorous and effective. Ether was injected, the head lowered, sponges wrung out of very hot water were applied over the heart, and electricity to the neck. In about five minutes the pulse was again to be felt and the man recovered. Had the rules laid down by the Hyderabad Commission for the administration of chloroform been carried out in these two cases, had the indications afforded by observation of the pulse been disregarded and the condition of the respiration alone noted, the chances are that the deaths of these patients would have had to be added to the already too long list of "deaths under chloroform." But, luckily, the cessation of the pulse was one of the danger signals which was being looked for, and on its appearance steps were immediately taken to prevent the catastrophe of which it was the first sign.

When the dangerous symptoms arose in these cases the attention of those present was called to the sequence of events—that the pulse had quite ceased to be felt, whilst not only did the movements of respiration continue, but that they were effective in moving the air freely in and out of the lungs. I lay stress on this latter point because it does now and then happen during anæsthesia that the respiratory movements are vigorous, whilst no air can enter the chest on account of closure of the glottis. The twisting of a portion of the peritoneum may have had some effect in producing the syncope in the second case, nevertheless, you may con-

sider this note worth publication as *apropos* to the most points in chloroform anæsthesia.

I am, Sirs, yours truly,

W. A. STEVENSON,

March, 1893 Professor of Surgery, Army Medical School, Netley

THE PRACTICAL WORKINGS OF THE "LEICESTER SYSTEM"

To the Editors of THE LANCET

SIRS,—I think the following illustration of the way this much vaunted "system" is carried out will interest and astonish you. On Monday morning (March 6th) I found two men suffering from small pox lying in one bed in a double bedded room in a thickly populated part of the town. As there were six children and a man lodger (as well as the two patients), besides the father and mother, in the house, I thought these cases ought to be removed to the fever house without delay and I made a special journey to the health office, thereby ensuring the removal of these patients twenty-four hours sooner than they would have been if I had followed the usual course of sending the notification by post. Having placed the authorities on such advantageous terms I determined to observe the application of the prompt and vigorous "isolation method" which Leicester employs to prevent the dissemination of small-pox, so thirty-six hours after the removal of the patients I called at the house and found that the authorities were burning sulphur there. The children were playing in the back yard, which was separated from other back yards by a 4 ft. wall, and the husband (who was a servant of the corporation) was told that he must not go to work, but that his wages would be paid and that he was to keep the children from mixing with others, he would, however, be allowed to take them after dark (*sic*) for a run in the Victoria Park (Leicester's right lung and the evening promenade of the people), and at night between 7 and 8 o'clock the husband and the four boys could take their prescribed walk. During some part of the day they are allowed to go and work on an allotment the husband has about a mile from the house, there are forty or fifty allotments adjoining his, and there is nothing to prevent the other holders and their children from going to work there. Last Saturday the husband was told that he could go to the town hall to draw his allowance, which he did, receiving a sovereign in lieu of wages whilst he was in "quarantine." Now comes the most remarkable incident of this "isolation system." The man who slept in the other bed in this double bedded room where the two small pox patients lay was allowed to go to work as usual and has done so ever since. He works at the Midland Railway tunnel widening, where over 200 men are employed. I am simply stating facts. I will make no comments, but in conclusion let me say that a greater mass of incongruities and a greater bundle of inconsistencies than this "Leicester system" never emanated out of Bedlam.

I am, Sirs, yours truly,

JOHN T H DAVIES, M D BRUX

Leicester, March 14th, 1893.

"OBSERVATIONS ON THE PREVALENCE OF TYPHOID FEVER AMONGST BRITISH SOLDIERS IN GARRISON IN EGYPT"

To the Editors of THE LANCET

SIRS,—I would feel obliged if you would give me space to make a few comments on Dr Mackie's article under the above heading which appeared in THE LANCET of Jan. 28th.

1 Dr Mackie's comparison between the relative prevalence of enteric fever amongst the British soldiers and the general population of Alexandria does not appear to me to be a just one. The population of Alexandria consists generally of Arabs, Levantines and other natives of the Mediterranean littoral, all of whom are born and bred in an atmosphere of insanitation and have been exposed to the contagium of enteric fever from infancy, at which age I believe it probable most of them pass through the disease, those that remain being the survival of the fittest. Such a view will account for the enormous infantile mortality in Alexandria and the apparent immunity of indigenous adults from enteric fever. For such a purpose the British soldier must be compared with persons of his own nationality and age. Roughly speaking, one soldier in ten contracted enteric fever during the

therein, 'shall be holder of a certificate showing that he has by examination shown himself competent for such office,' is of opinion (1) That this new enactment is calculated to afford an important additional safeguard to the public health, (2) that it should be extended to the Health Acts applicable to the United Kingdom generally, (3) that a central board of examiners should be formed to conduct the necessary examinations and grant certificates in connexion therewith, and (4) that the constitution of the board of examiners should be subject to the approval of the Local Government Board in England and Wales, the Local Government Board in Ireland for Ireland, and the Board of Supervision in Scotland." I would add that this Institute attaches far more importance to the training of sanitary inspectors than to their examination, but it has no desire that they should receive a "quasi medical knowledge" or in any way be educated out of their proper position.

I am loth to introduce any point of a controversial character into this letter, but it is right that it should be known that the position is at present complicated by the Sanitary Institute endeavouring to obtain a Royal Charter of Incorporation, the application is being opposed by the British Institute of Public Health, in common with the Incorporated Society of Medical Officers of Health, the Plumbers' Company, the Institute of Civil Engineers and other bodies. So far as we are concerned, we feel that it would be unfair and inexpedient, and not in the public interest, to give any single sanitary institute or society such a prestige as is thus sought, to the prejudice of other allied and not less important bodies, especially in view of the negotiations which must take place for the formation of a single examining board.

I am, Sirs, yours truly,

WILLIAM R. SMITH, M.D., D.Sc., F.R.S. Ed.,
Chairman of the Council

Hanover square, W., March 7th, 1893

Our correspondent is "at a loss to understand on what authority" we say "there is no reason for believing that the Sanitary Institute desires to retain a monopoly of the examination or to prevent the constitution of some other body to undertake this important work." We would ask him what authority has anyone for assuming that the Sanitary Institute has such desire? For our own part, we have regarded the Institute as consisting of gentlemen who, in the absence of a better qualified body, have undertaken a useful work, and we are certainly not prepared, without a shadow of evidence, to assume that these gentlemen are desirous of adopting a course which we believe would not be to the public interest. We note that Dr Smith does not attempt to give any explanation of the omission to send cards of invitation to the meeting at the Mansion House to members of the council of the Sanitary Institute, an omission to which Dr Corfield and others called attention in the public press and to which we alluded in our article.—ED. L.

INSANITARY SCHOOLS

To the Editors of THE LANCET

SIRS,—An allegation is made as to the insanitary condition of one of our public school buildings in this town. Curiosity is given to a report that, owing to the presence of stagnant water underneath its floor, it was unhealthy. The school board members immediately had the flooring taken up for investigation. Water was discovered covering an area of something like twenty square yards, having a depth of six inches in the centre. The water is as clear as crystal, and perfectly sweet, even the sediment at the bottom is sweet. There is an excavation of three feet below the floor, which is properly ventilated. The flooring boards and joists are perfectly dry, and the walls show no sign of dampness whatever. The building (a comparatively new structure fulfilling in every way the requirements of the Board of Education) is built partly on a rock, which had to be blasted. It appears that a natural spring oozed from this rock, which, no doubt, accounts for the water. I may also add that after a fortnight of dry weather this water had subsided four inches in depth and covered an area of only ten square yards. To drain this water will entail a very heavy outlay. Will you

kindly express your opinion on the matter? Is the presence of this water a source of danger to the health of the children?

I am, Sirs, yours faithfully,

Llanrwst, North Wales, March 11th, 1893. GEORGE WILKINSON

There cannot be a doubt that the presence of such a sheet of water beneath the flooring of a building must be a source of danger to the inmates. The fact mentioned in the letter that the source of the water is probably a natural spring also makes it certain that unless steps are taken to remedy the existing state of affairs the risk to the children will be constant. Certainly the clearness and sweetness of the underground water may be looked upon as fortunate, but they do not abolish the dangers of dampness. Equally sure is it that the absence of damp from the walls at present is no guarantee for their dryness in the future. We should strongly recommend that the expense of subsoil drainage (however great) should be incurred, and the basement of the building should be covered with six inches of concrete.—ED. L.

"ISOLATION" & "INUNCTION"

To the Editors of THE LANCET

SIRS,—Dr Thresh, in his letter published in THE LANCET of March 4th, implies that I was the author of, or in some way responsible for, some letters in the Hitchin local papers in November last on the subject of infectious hospitals. I am not responsible for anything published in the Hitchin papers, and I had no communication with anyone at Hitchin until I received a letter from a gentleman residing there in February, who was unknown to me, asking for information on the subject of antiseptic inunction. This I replied to and on Feb. 14th I received a letter from him telling me of "the abandonment of the scheme" for building a hospital, "at least, for some time to come." I may have mentioned Chelmsford in my letter to him as one of the places where inunction was used, and I now regret that I had not written and asked Dr Thresh for particulars, as in every other instance I have done, instead of trusting to the communication of a third person. I have never mentioned Dr Carter's name in relation to the matter. In 1891 the Enfield Board proposed to build a hospital, they were advised to try the inunction method of disinfection first. They did so and the hospital is not yet built. Dr Ridge has always declined to give me any information as to the results of its use. In his last letter to me in December he says "I am not prepared to give you any evidence with regard to the use of the eucalyptus. I have no means of knowing whether it has been properly used, but it is certainly not an infallible preventive in practice." If it be left entirely to the sanitary officer to leave a bottle at each house, with verbal directions to the mothers, how could this or any form of disinfection be infallible? I know that the only precaution taken has been the separation of the other children of the family from the patient. They have not been subjected to the disinfectant precautions mentioned by me in my papers. There is no reason why antiseptic inunction, if properly carried out, should not be as successful in the hands of Dr Ridge or Dr Thresh as it has been during the last three years in the hands of many others. These two gentlemen are the only persons from whom I have received any adverse opinion as to the perfect success of antiseptic inunction by the eucalyptus disinfectant in arresting infection. I only ask for a fair trial of inunction, accompanied with all necessary precautions with regard to other children who may have been exposed to the infection and as regards infected clothes, toys &c., but this I fear I must not expect at the hands of the advocates of the hospital system, although that system has proved a disastrous failure, as shown by some facts and figures lately published. The average cost of each patient admitted into an infectious hospital ranges from £5 to £30, exclusive of the cost of the building and site, and the returns from the London Asylums Board show that with all their efforts and the expenditure of over £100,000 in six months they have not in the slightest degree checked the progress of the epidemic of scarlet fever. For on April 2nd last there were 1227 cases in the hospitals, and last week there were 2293, the figures in the interim having never receded to the former number. This is a serious matter for the consideration of the ratepayers, and one requiring the

investigation of the Local Government Board before £50 000 more is spent on building a hospital at Tooting. To return to Dr. Thresh, whose letter would lead your readers to believe that I have made other false statements. At Bexley it was proposed last June to build a hospital, but it was decided to try the inunction method first. The hospital is not built, and Dr. Sunderland, in a letter to me in December, says, "I have used the eucalyptus plan in all cases of scarlet fever under my care since I saw you (in July) and have had no spread of infection" then why build a hospital? The epidemic there was brought to a close with 157 cases, these if treated in a hospital would have cost the ratepayers £1700 but if the whole had been treated by antiseptic inunction the cost would not have exceeded £40. I have not at any time, as implied by Dr. Thresh, stated that Mr. Hayward of Haydock was using inunction to the exclusion of isolation. In his letter to me that gentleman says "I have certainly seen, since employing this treatment, several cases where the disease (scarlet fever) did not spread to other children of the family who were not protected by a previous attack and where no strict isolation was possible." I cannot trespass further on your valuable space, as all who desire information on the subject can obtain it from my published papers or from the reprint of my last paper from the *Medical Magazine*. It is impossible for me to ascertain who have been using this method of disinfection, but I hope that those who have tried it will not fail to communicate their experience of it to the profession.

I am, Sirs, yours faithfully,

Teddington, March 9th, 1893.

J B CURGENVEN

"DEATHS UNDER CHLOROFORM"

To the Editors of THE LANCET

SIRS,—I crave your indulgence whilst I make a few remarks on the letters which have appeared under the above heading. Like Dr. Edgewell, I was much struck with the case published above my letter by Mr. Rowlands because of its apparent *à propos*ness to my remarks. However I demur to it as an illustration of the "open method" since the exhibition of an anæsthetic on lint is not the same thing as a folded towel. Dr. Haughton exactly expresses my thoughts when he calls the use of lint "simply an abomination," and Dr. Robinson Hill has directed attention to Syme's condemnation of its use. The essence of the use of the folded towel is to ensure an admixture of air and chloroform which varies with the stage of administration, the amount of the former being slight at first, and then, as anæsthesia becomes established, there is a larger quantity of air permitted access. This is readily managed by bringing the towel nearer to or farther from the face, according to whether it is desired to let the patient come out or to put him more decidedly under. There is another point requiring special notice, and this is strikingly emphasised in a letter from Mr. A. Neve, where he relates a case under his own care. This point is that there is more danger of giving too little chloroform than too much. It would be interesting if a record could be obtained of the number of deaths, if any which have occurred in the Edinburgh Infirmary since Syme's day. I never heard of one myself all the time I was in Edinburgh. I throw out this suggestion, not because I would be disposed to base any argument upon statistics merely but as a species of corroborative evidence. In conclusion, I trust this matter will not be allowed to rest in its present unsatisfactory state. Let there be some authoritative dictum.

I remain, Sirs, yours sincerely

G A. VAN SOMEREN, M.D. Edin.

Orange New South Wales Feb 4th, 1893.

SMALL-POX AT LEICESTER

To the Editors of THE LANCET

SIRS,—In view of the "statements" that are appearing in the medical and lay papers as to small pox and the staff at the Leicester Fever Hospital, allow me to give you the following facts. At the time of the small pox outbreak our fever hospital staff consisted of 1 medical officer, 1 matron, 15 nurses, 1 cook, 3 wardmaids, 4 laundresses, 1 stoker, 1 porter and his wife—making 28 persons in all. Of these 28, 22 were protected either by a previous attack of small pox or by revaccination (including 8 whom I revaccinated) whilst the remaining 6 had only been vaccinated in childhood and so were not 'efficiently' protected. Of

these 6 'inefficiently' protected officials, all of whom refused revaccination which I offered them, 4 have since contracted small pox and 1 has died, so that 2 only of the staff now remain 'inefficiently' protected, and it will be interesting to note their future histories. The 4 recent additions to our hospital staff have now been revaccinated. One nurse (said to have been revaccinated ten years ago) has suffered from a doubtful attack of modified small pox (half a dozen spots in all, and these abortive), and, curiously enough, she too refused revaccination when our small-pox broke out. I am unable to ascertain whether or not her revaccination was efficiently performed. Her case (if small pox at all) would seem to point to the advisability of even revaccination being *re-done* in times of epidemics." The above is an extract from a report already in the hands of the printer.

I am, Sirs, yours truly,

JOSEPH PRIESTLEY,

Medical Officer of Health.

Leicester, March 10th, 1893.

HOW UNION APPOINTMENTS ARE MADE

To the Editors of THE LANCET

SIRS—Frequently in THE LANCET and elsewhere are advertised vacancies for medical officers to various unions. Will you allow me through its columns to point out what a farce these elections are? As a matter of fact nearly all these appointments are cut and dried, and the man who buys the practice or death vacancy, as the case may be, practically buys the appointments as well. I do not so much grumble at this, but what I object to is the fact of boards of guardians asking for applications and then not even troubling to have the applicants before them when the appointment is made, which is frequently the case. In my personal experience I have been a candidate for two union appointments, in the first instance I bought the practice (the union appointment connected with it was not even advertised) and I was of course elected. This may be illegal, as I believe all union appointments are supposed to be advertised, but in my opinion it is far preferable not to do so than to advertise an appointment already practically filled up. In the second instance I was one of six applicants and the board, after advertising the appointment and asking for testimonials did not wish to see any of us at the election and eventually appointed the man (a foreigner) who had bought the practice. What, then, is the use of applying for these posts as the elections are at present conducted? If boards of guardians really wish to appoint the most suitable man they certainly ought to have the candidates before them and consider carefully every application. At present the whole thing is a farce, and a man who buys a practice and has been qualified only a week stands a better chance of the appointment than one who has had ten years' experience and has held a similar post. Trusting you will insert this letter and enclosing my card,

I am, Sirs, yours truly

Feb 22nd, 1893.

M R C P

MANCHESTER

(FROM OUR OWN CORRESPONDENT)

Enlargement of the Medical School at Owens College

THE half yearly meeting of the council of the Owens College was held on the 7th inst., at which a report was presented showing the attendance of students in the several departments. The total number of day students was given as 941, of which 356 were medical (as compared with 389 at the corresponding date of last year). One of the causes of this falling off in the number of medical students is believed to be the insufficient accommodation at present available in the existing medical school buildings. The fine new buildings for this school are fast progressing towards completion under the direction of Mr. Alfred Waterhouse, architect to the college. The subscriptions received towards the building fund of this part of the college now amount to rather more than £20 000 which is very far short of the probable requirements of the scheme. The report proceeds—'At a time when the college is incurring heavy responsibilities on behalf of its medical school and is involved in a steadily increasing annual expenditure on account of the natural history museum, it is cut off by lack of funds from other important developments necessary to its progress in the departments of arts and

science. Under these circumstances the council regretted to learn that the Chancellor of the Exchequer has felt himself compelled to decline to receive a deputation on the subject of an increased Government grant to University Colleges, such as was explicitly recommended in the report of the Committee of the House of Commons, ordered to be printed March 21st, 1892." The report further states that the Queen's gift of £2000 out of the funds of the Duchy of Lancaster is to be applied towards the cost of a site for the women's department of the college.

Schorlemmer Laboratory

The friends of the late Professor Schorlemmer, F.R.S., are raising funds for the erection at Owens College of a new organic chemistry laboratory bearing his name. On completion this laboratory will be presented to the college, and will further enrich the already splendid laboratory equipment of that institution. The college has undertaken, in the event of suitable plans being submitted, to provide an appropriate site for the purpose.

Violent Conduct of a Patient in Hospital

On Tuesday last, at the City Police Court, a young man who had just been discharged from the small pox hospital at Monsall was charged at the instance of the sanitary authorities with exposing himself and his clothing in the public street whilst suffering from a dangerous infectious disease, and also with doing wilful damage to the hospital buildings. It appears from the evidence that on the 2nd inst. the defendant was a patient at the Monsall Hospital, suffering from small pox. He was allowed to take exercise in the hospital grounds, but was specially cautioned not to go beyond them. He, however, effected his escape from the hospital, and ran some distance along the streets, through which many people were passing at the time. Dr Berry, the medical superintendent of the hospital, promptly gave chase to the fugitive patient and had the good fortune to find him and to induce him to return to the hospital. On being placed again in the small pox ward the man at once became violent and abusive and threatened to assault both nurses and doctors. He went into the ward lavatory and, after fastening the door, began to smash the window and to otherwise misconduct himself. Medical evidence went to show that during the defendant's stay in hospital he was a very unruly patient and caused considerable trouble. On being asked by the magistrates why he had committed these outrages, the defendant said that he was very sorry for his misconduct, but that he was not accountable for his deeds whilst in hospital, for he did not know what he was doing, he was "wrong in his head." Dr Berry, however, was able to satisfy the bench as to the patient's perfect sanity, and the magistrates sentenced the man to a fine of 15s and costs, or fourteen days' imprisonment as an alternative.

The Small pox Epidemic

Small pox still continues to spread in the community of which Manchester is the centre but in the city itself fewer cases were reported during the week ending Saturday, March 4th, than in any week since the commencement of the year. In the week ending on Saturday last, however, 24 cases were reported, against 10 only in the preceding week, and the medical officer of health reports after personal inspection of the patients, that the type of the disease still continues to be severe. Many of the cases are confluent or semi confluent, and not a few are of the hæmorrhagic variety, consequently the case fatality is considerable. The number of cases in hospital on Saturday last was 155, as compared with 189 at the end of the previous fortnight.

The Wilington Hospital

Mr Justice Chitty has now given judgment in the case of the Attorney General v the Mayor and Corporation of Manchester. His lordship said this was the third motion against the Manchester Corporation on this subject. The ground of the motion was an apprehended public nuisance—an apprehended danger to the public health. His lordship quoted recent statistics of small pox prevalence in Manchester which showed that there were still grounds for apprehension in regard to its further spread. He was of opinion that the allegation that the corporation had acted wantonly in the matter was not justified. Each side had produced reputable witnesses competent to speak on the subject of small pox and of small pox hospitals, and his lordship did not impugn the good faith of these witnesses. In his opinion the evidence in favour of the plaintiff's case was not sufficiently cogent to make the question of granting an injunction turn on

the balance of convenience or inconvenience, and taking all things into consideration he had arrived at the conclusion that the plaintiff had failed to show that the apprehended danger would infallibly ensue. His lordship was of opinion that the court should exercise great caution before using a power which might tend to close many well ordered hospitals. The motion was therefore dismissed and the injunction was refused.

Manchester, March 14th

BIRMINGHAM

(FROM OUR OWN CORRESPONDENT)

The General Hospital

THE 113th annual meeting of this institution was held on the 15th inst., under the presidency of the Earl of Dartmouth. The report showed that £1039 more had been spent this year, mostly in cleaning and painting the old building. During the past four years the in-patients had increased by 20 per cent. and the out-patients by 10 per cent. In the last twenty years the number of in-patients had increased by no less than 64 per cent and the out-patients had doubled. The nursing arrangements had also been considered, much to the comfort of the nurses. Dr Wade was appointed consulting physician, Mr W. T. Smedley was elected a life governor. The usual votes of thanks were passed.

Ingledby Lectures

Dr Carter, the appointed lecturer for the year, has arranged to give a course of three lectures on Diarrhoea and Constipation in Childhood. The first and second were well attended and listened to with much interest.

Mason College

Dr Savage has been appointed Professor of Gynecology in the college. He has been for many years senior surgeon to the Women's Hospital. He was the only candidate. Mr Oliver Pemberton was elected Bailiff of the college at the same meeting.

Athletic Institute

The last of a series of health lectures is to be given by Sir J. Crichton Browne on the 18th inst., the subject being Heredity. This institution is in a flourishing condition and is popular among the young people of the city, exercises and recreation are also provided for the middle aged.

March 15th.

NORTHERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENT)

The Fleming Memorial Hospital (Newcastle) for Sick Children

In my notes which appeared on Feb 18th last, referring to the annual report of the Children's Hospital, Newcastle-on-Tyne, I said that there was no mention made of the death-rate, which was considered by some as being excessive. This statement I am glad to correct. The mortality due to operations has been 9, or at the rate of 2.7 per cent., whilst the total mortality of the hospital has been at the rate of 5.65 per cent., against 7.89 in the previous year.

The Spread of Small-pox

Dr Edward Jepson of Durham has a very pertinent letter about the spread of small pox in one of our local papers. He shows how outbreaks of the disease have followed the admission of tramps into the Durham gaol, and he urges upon all guardians and members of sanitary boards to lay the importance of vaccination before the Local Government Board, so as to have all tramps admitted into gaols and workhouses efficiently vaccinated with calf lymph. Dr Jepson thinks if this rule were enforced for one month the disease would be stamped out. Cases of small pox are reported from Wigton, Penrith, Workington, Kendal and Grasmere. As before, the cases have been solitary ones, introduced by tramps or wayfarers and have been promptly dealt with by the sanitary authorities.

Sunderland Lunatic Asylum

It is stated that the Sunderland Corporation have definitely decided to light their new lunatic asylum now in course of erection at Ryhope, with electricity. It is said that the

initial cost will be about £1500 more than gas, but there will be a saving in the long run, as the working expenses will be £175 less per annum.

Sudden Death of Dr George Hood of Tow Law, co Durham

The death of Dr George Hood of Tow Law is announced. Dr Hood, who had been for some time indisposed and confined to his house, dined with his family on Sunday last, but a few minutes after retiring to bed he expired from cardiac weakness. Dr Hood, who was a graduate of Edinburgh University, was about fifty five years of age and had practised in Tow Law over thirty years.

Bequest to Whitehaven Infirmary

Mrs. Robertson, late of Gulgarron, has left by her will about £600 to Whitehaven charities, including the Whitehaven and West Cumberland Infirmary.

The Proposed Floating Hospital for the Tees

It was last week resolved by the Tees port sanitary authority to borrow £7000 to build the proposed floating hospital from the designs of Mr Laws, city engineer Newcastle.

Death under Chloroform at South Shields

A death took place the other day in the case of a patient who was placed under chloroform for severe injury to his leg, sustained by a grating becoming loose on board a ferry steamer. It was shown that the chloroform was carefully given and that shortly after entering the stage of excitement he suddenly ceased breathing and died. The patient was a travelling jeweller aged forty nine. Drs Gibbon and Sutherland and Mr Crisp were engaged in the case and agreed in their testimony. The coroner at the inquest, in commenting on the case, said that the percentage of deaths from the use of chloroform was very small indeed.

Newcastle-on Tyne, March 15th.

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

Association for the Promotion of Reform in Medical Education

AFTER a long period of inactivity this Association is again making its existence known, the Executive having called a meeting of it to consider a draft report on the Financial Ordinances issued by the University Commissioners. The report, as prepared by the Executive, examines the draft ordinance very critically and is frank and unsparing in its condemnation of what the Commission proposes to do, but chiefly of what it leaves undone. The result of the meeting will be referred to next week.

Female Medical Practitioners and the Edinburgh Medical Societies

Some time ago a female medical practitioner of medicine in Edinburgh asked for an application for membership to the Medico-Chirurgical Society. The matter was brought before the Society, and as there was no law against admission notice was given of a motion to modify a law, so that only male practitioners should be eligible for membership. This was carried by a large majority. The same lady applied for admission to the Obstetrical Society, and as she was proposed and seconded and no law existed to exclude her she was balloted for, but not admitted. A majority of two-thirds is necessary for admission to this Society. The feeling in both societies was that the presence of women would more or less hamper freedom of speech, and this was felt by many members who were quite friendly towards them from the educational standpoint.

Closes of the Winter Session

The session of the medical classes in Edinburgh closes on Friday, the 17th inst. The First Professional Examination at the University begins on Monday next and the Second Professional Examination on the following Monday.

Inspection of Dead Meat in Edinburgh

Last week it was under the notice of a subcommittee of the Public Health Committee of Edinburgh that it had become a custom to send dead meat to the slaughter houses addressed to the superintendent and marked 'for inspection', if passed to be handed to — (here the name of a salesman being entered). It was observed that this opened a wide door for dishonest traders endeavouring to palm off on the public meat which they knew to be diseased, that

the slaughter houses were not intended for the reception of dead meat, and that it put too much power into the hands of the superintendent, who might be a person with no special knowledge of the diseases from which cattle died. The subcommittee were unanimously of opinion that the practice should be discontinued and that public notice should be given of the same.

The Edinburgh City Hospital

At the meeting of the Edinburgh Town Council last week it was reported that there were 260 patients in the City Hospital and 17 cases of small pox in the small pox hospital, and that the epidemic of measles and scarlet fever was subsiding. At the same meeting a deputation was appointed to visit some other towns to inspect their infectious diseases hospitals with a view to obtaining information as to the alterations and additions to be made at the Edinburgh City Hospital.

March 14th.

IRELAND

(FROM OUR OWN CORRESPONDENT)

Royal College of Surgeons

A MEETING of the College has been convened for the 18th inst. by the vice-president of the College, in the absence of the president, to consider the "Government of Ireland" Bill at present before Parliament, as affecting the future state of the College and the position and interests of its Fellows and Licentiates. The meeting is called consequent to a requisition signed, among others by Sir G. Porter, Bart., Sir Philip Smyly and Sir William Stokes.

Report of 112 Abdominal Sections performed in the Rotunda Hospital

Dr W. J. Smyly, Master of the Rotunda Lying-in Hospital, read a report recently at a meeting of the Royal Academy of Medicine, on 112 Abdominal Sections. There were 43 ovariectomies, with 7 deaths, and 47 hysterectomies. In 5 cases he performed total extirpation of the uterus, freeing the cervix per vaginam, and subsequently removed the entire organ by abdominal section. One of these patients died. In two cases this method was adopted because of malignant disease of the mucous membrane—in one, malignant adenoma; in the other carcinoma. Both these women are now alive and well. Porro's operation was performed on a patient with rupture of the uterus extending into the posterior fornix of the vagina, with a fatal result. An umbilical hernia was operated on by Sanger's modification of Mr Lawson Tait's flap-splitting method. In this the fibrous ring surrounding the opening was split with scissors and the flaps thus formed were turned outwards and inwards, the deeper ones being united by a continuous catgut suture and the superficial by an interrupted suture. The result was excellent.

Medical Magistrates

Dr John Hegarty has been placed on the Commission of the Peace for the county Galway, also Dr James Trant and Dr Stoker for the county Kerry.

The Sanitary Institute in conjunction with the Corporation of Dublin

The eleventh provincial course of lectures and demonstrations for sanitary officers and others will commence in Dublin on the 18th inst., when the introductory lecture to the series of twelve lectures will be delivered by Sir Charles Cameron. The other lecturers will include Sir Douglas Galton, K.C.B., Mr Francis Vacher, Professor Antony Roche and Mr Edgar Flinn. These lectures will be illustrated by diagrams, models and drawings and they have been arranged for the special instruction of those desirous of obtaining knowledge of the duties of sanitary officers.

March 5th.

FOOTBALL CASUALTIES—Whilst playing a game in the playground attached to the Green Lane Board School New Worley, on the 9th inst., a schoolboy fractured his leg and has been admitted to the Leeds Infirmary. On Saturday last during a match on the Leeds Institute ground, a player fractured his leg and was removed to the Leeds Infirmary. On the same day in a match at Horsforth between Woodside St. James and Armley A. Team, a player fractured his leg.

Obituary.

J DAVIES THOMAS, M D LOND, F R C S ENG
OF ADELAIDE.

INFORMATION has just been received of the lamented death of Dr J Davies Thomas, which took place at Adelaide on Jan 30th after a long illness and at the early age of forty nine. His medical education commenced at University College, London, where his studentship was marked by more than ordinary assiduity and successful competition for prizes within his reach. After completing his curriculum he obtained the licence of the Apothecaries' Society and subsequently the membership of the College of Surgeons. In the same year (1867) he passed the first examination for the M B Lond. Two years later he gained the licence of the College of Physicians, passed the second examination for M B, and graduated M D Lond after having obtained the F R C S Eng. Having thus become fully equipped for the career he proposed to follow, he sought and obtained the posts of resident medical officer of University College Hospital and resident clinical assistant at the Brompton Hospital, serving also at the former hospital under Sir William Jenner and Dr Russell Reynolds. Ardent devotion to his duties, however, soon resulted in failure of physical power, and in 1875 the subject of our notice was compelled to leave London and take a voyage to Australia. After a few weeks' residence in Victoria he was appointed senior house surgeon in the Adelaide Hospital, a post which he, however, resigned to the great regret of the other members of the hospital staff. At Adelaide Dr Thomas occupied many important posts with great acceptance. He was joint lecturer with Dr Verco on Medicine at the University, and for eight years was a member of the council. His literary work does not appear to have been extensive, though but for the paralytic attack which prostrated him many months ago an important work upon which he was engaged would doubtless have appeared. One book of his, on Hydatids, a subject to which he devoted much study, has been published and is highly spoken of. The profession in South Australia have to mourn the loss of a distinguished confrere, and the patients who came under his care that of a sagacious physician and a sympathising friend.

THE CROONIAN LECTURE OF THE ROYAL SOCIETY

A BRILLIANT and distinguished audience assembled in the theatre of the University of London to listen to the Croonian Lecture delivered by Professor Virchow before the Royal Society on Thursday, March 18th. The President of the Royal Society, Lord Kelvin, conducted Professor Virchow into the Theatre amid manifestations of cordial welcome.

The subject of the lecture was a review of the history of pathological science, more especially in its bearings on the question of the doctrine of life. It is published *in extenso* in another column. The concluding sentence, "May this union never be broken," was greeted with loud applause, the lecturer referring to the scientific union which had endured between English and German investigators for more than three hundred years.

At the conclusion of the address, which occupied one hour and a half in delivery, and which was delivered in English, Lord Kelvin called upon Sir Joseph Lister to move a vote of thanks to Professor Virchow. Sir Joseph Lister, in doing so said "We hardly know whether to admire most the erudition, the wisdom, or the eloquence which has been displayed. To hear this prince of pathologists speaking amongst us has been a very great treat. An account of the wonderful history of the advance of pathology from the earliest times, culminating in his own great contributions to that advancement, must have afforded the greatest satisfaction to all who heard him."

Dr Samuel Wilks, as an old student of pathology, seconded the proposition "Professor Virchow," he said, "had been our great master in England for many years. To him pathology was mainly indebted, and through the pathologist the medical profession at large, perhaps, was indebted to him

more than to any other man in the scientific world. Professor Virchow had been his master for all his life, a statement which might appear very remarkable, seeing that both of them were pretty nearly of the same age, but that only showed how early Professor Virchow had begun to make himself felt in the scientific world."

Professor Michael Foster then asked Professor Virchow, as he had delivered his address in English, to address a few German words from his true German heart. In complying with this request Professor Virchow, speaking in German, said in effect that England had not lagged behind the other nations in the world in the pursuit of science, that was in a great measure due to the freedom which was allowed to that pursuit in England. In the domain of political freedom England stood far ahead of Germany. England, he said had never lacked freedom to undertake and pursue science, but, now that Germany had partly obtained this advantage, he trusted that his native land would be able to keep pace with the progress of science in this country, and the two countries would be united in closer bonds, which he hoped would never be broken.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentleman having previously passed the necessary examinations and having now conformed to the by laws and regulations, was at the ordinary meeting of the Council on Thursday, the 9th inst., admitted a Member of the College —
Hill Charles Alex., student of Cambridge University and St. George's Hospital.

ST MARY'S HOSPITAL ATHLETIC SPORTS DINNER. Mr Henry Juler presided at this dinner, held on March 9th at the Criterion Restaurant. There were 117 present, including Sir Edward Sieveking, Dr Farquharson, M P, Dr Braxton Hicks, F R S, Dr Danford Thomas, Dr Alder Wright, F R S, Mr Herbert Page, Dr Sidney Phillips, Dr Waller, F R S, Dr Handfield Jones & Co Staff Surgeon Theodore Preston, R N, responded for "The Navy," Brigade Surgeon Myers for "The Army," and Dr Danford Thomas for "The Reserve Forces." Dr Farquharson, M P, gave the toast of "The Staff," and the Dean, Mr G P Field, replied. The chairman gave the toast of the evening, and Messrs Poynton, Mould, Bond and Collier returned thanks for "The Cricket, Athletic and Football Clubs." The chairman's health was proposed by Mr A J Pepper. The musical arrangements were admirably carried out by Messrs J E Lane, Marcus Johnson, W Marshall and E Staples.

THE LEVÉE.—On Monday last the following presentations were made, on behalf of Her Majesty, to H.R.H. the Prince of Wales at St. James's Palace.—Surgeon Lieutenant R. F. E. Austin, Army Medical Staff, by Lieutenant General Sir H. E. Wood, V C, G C B & Co, Surgeon Lieutenant H. A. Bray, Army Medical Staff, by Lieutenant General Sir E. Wood, V C, G C B & Co, Surgeon C. L. W. Buntton, M B, R N, by the Medical Director General of the Navy, Surgeon A. S. G. Bell, R N, by the Medical Director General of the Navy, Fleet Surgeon A. T. Corrie, R N, by the Medical Director General of the Navy, Surgeon Major E. R. Cree, Army Medical Staff, on promotion, by Lieutenant General Sir H. E. Wood, V C, G C B & Co, Medical Director General J. N. Dick, C B, R N, on appointment as Hon Surgeon to Her Majesty, by First Lord of Admiralty, Surgeon Major P. M. Ellis, Army Medical Staff, by Lieutenant General Sir E. Wood, V C, G C B, Surgeon R. J. Fyfe, R N, by the Medical Director General of the Navy, Deputy Inspector General J. W. Fisher, M D, R N, on promotion, by the Medical Director General of the Navy, Surgeon Lieutenant G. Y. G. Hunter, Indian Medical Service, by the Secretary of State, Surgeon Major L. Hall, Army Medical Staff, on promotion, by Director General A. M. S., Surgeon G. Ley, R N, by the Medical Director General of the Navy, Surgeon F. D. Lumley, R N, by the Medical Director General of the Navy, Surgeon P. Lord, M B, R N, by the Medical Director General of the Navy, Surgeon Lieutenant J. P. Morton, Indian Medical Service, by the Secretary of State, Surgeon Major General Sir W. A. Mackinnon K C B, Director General Army Medical Staff, on appointment as Honorary Surgeon to the Queen, by the Adjutant-General, Surgeon P. M. May, R N, by the Medical Director General of the Navy, Surgeon E. T. Meagher, R N, by

the Medical Director General of the Navy, Surgeon Major T. H. Parke, Army Medical Staff, on promotion, by the Director General Army Medical Staff, Sir W. Stokes, M.D., on appointment as Surgeon in Ordinary to Her Majesty in Ireland, by the Lord Chamberlain, Surgeon Lieutenant N. Tyacke, by the Director General Army Medical Staff, Surgeon Lieutenant A. F. Tyrrell, Army Medical Staff, by Lieutenant-General Sir E. Wood, V.C., G.C.B., G.C.M.G., Surgeon Captain C. R. Tyrrell, Army Medical Staff, by Lieutenant-General Sir E. Wood, V.C., G.C.B., G.C.M.G., Surgeon H. E. Tomlinson, R.N., by the Medical Director General of the Navy, and Surgeon Lieutenant C. E. Williams, Indian Medical Service, by the Secretary of State.

UNIVERSITY OF OXFORD—On Tuesday the honorary degree of M.A. was conferred in Convocation on Mr. John Scott Haldane, M.B. Edin., assistant in the physiological department of the University Museum. On the same day the members of Convocation were engaged in discussing a proposal to request the Radcliffe Infirmary authorities to repay the £500 which had been granted in 1869 as a contribution towards the erection of fever wards. It was contended that, the wards having been recently closed, the members of the University would no longer have the accommodation thus provided. The Master of University College, as treasurer of the infirmary, said the closing of the wards was necessitated by disciplinary difficulties and by the erection of a City hospital for the reception of infectious diseases. Professor Pelham said the University had for twenty years enjoyed the benefit of the arrangement with the Radcliffe Infirmary, and it would be incredibly mean on the part of the University to withdraw the grant. The proposal was thrown out by 61 votes to 49.

PRESENTATION TO DR. W. SEDGWICK SAUNDERS—The Master of the Broderers Company (Dr. J. L. H. Langdon Down), the Wardens and the Court of Assistants assembled at the Albion, Aldersgate-street, on Monday, to pay a tribute of esteem to the late Master (Dr. W. Sedgwick Saunders, Medical Officer of Health for the City of London). The presentation took the shape of a beautifully illuminated address, artistic in colour and design. The Master, in making the presentation, said Dr. Sedgwick Saunders had occupied the position as Master of the Broderers Company for four years, and had done so with great usefulness, courtesy and distinction. The clerk of the company read an address which spoke of the high esteem in which Dr. Sedgwick Saunders was held by the Court and of the value of the services which he had conferred on the Company as well as on the citizens of London in general. Dr. Sedgwick Saunders, in accepting the gift, expressed his satisfaction that a gentleman occupying so distinguished a position in his profession should have made the presentation.

DISPROPORTIONATE STIPENDS OF POOR-LAW MEDICAL OFFICERS—At the weekly meeting of the guardians of the Strand Union, on Tuesday night, Mr. James Willing, jun., proposed that the salary of Mr. Jones, medical officer of the workhouse at Edmonton, be increased from £150 to £175 per annum, and pointed out in his speech the disproportions between the stipends paid to their medical officers by several metropolitan unions and boards of guardians and the numbers of the patients whom they had to attend in the different establishments. In Brentford Workhouse for professional attendance upon 570 inmates the medical officer's remuneration was £150 a year, Hampstead, 314 patients, £130, Homerton, 683, £140, Paddington, 623, £148, Westminster, 645, £150, Edmonton Local Workhouse, 480, £150, Holborn, 1331, £250, and the Strand, with 2852 juvenile and adult inmates, £150 a year! These figures were, in his opinion, eloquently expressive of the justice and necessity for the very moderate increase he now asked the Board to make in the annual stipend of their medical officer whose salary when compared with other metropolitan and suburban unions and establishments, was far from commensurate with the necessarily onerous and responsible duties he had to perform amongst such a large number of sick poor. The subject had been under consideration twelve months ago, when it was agreed to give Mr. Jones an increment of £25 a year in his salary, but on that occasion the Local Government Board suggested that it should take the form of a gratuity and not as an augmentation of his stipend. Mr. Dodson seconded the resolution which was supported by other guardians, who expressed the opinion that Mr. Jones was not sufficiently remunerated for his services in the workhouse schools and other establishments of a large and populous district like that of the Strand, especially when it

was remembered that in the neighbouring Poor Law Union of Westminster, with one-fourth less in number of people to attend, the medical officer received the same salary as Mr. Jones, £150 a year. The motion was carried unanimously.

NOTES IN PARLIAMENT

In the House of Commons a Bill for the Sanitary Registration of Dwelling houses, Schools, Hospitals, Factories, Lodging houses, and other buildings has been brought in by Mr. Martin Sir A. Borthwick, Dr. Cameron, Dr. Farquharson and Mr. Isaacson. The Bill is to come into operation on Jan. 1st, 1894. The local authorities, charged with the administration of the Public Health Acts, are to become sanitary registration authorities under this Act, who are to severally appoint a sanitary registrar. Each authority of the kind specified is to issue notices to owners or occupiers in its district, informing them of the provisions of the Bill, and that they may cause to be deposited with the authority a certificate setting forth that the sanitary arrangements are satisfactory. The Local Government Board or other responsible body is empowered to issue licences to members of associations concerned with sanitary science and to grant certificates of competency in sanitary practice. After the passing of this Bill it shall be unlawful for any building newly erected to be let or occupied until the sanitary arrangements have been duly certified. The term for which the certificate shall be regarded as valid shall be five years. The sanitary registration authority is to decide what buildings are being used as schools, colleges &c. within the meaning of the Bill. Finally the new Bill is not to interfere in any way with the Public Health Acts and with the powers possessed by local authorities in respect of public health.

Medical Officers of Health and Private Practise

On Monday Dr. Farquharson will question the Secretary for Scotland (Sir George Trevelyan) as to the truth of the report that he is about to rescind the rule laid down by his predecessor, that county medical officers of health in Scotland are debarred from engaging in private practice.—Dr. Farquharson will appeal to the right hon. gentleman not to interrupt the working of the rule until he has instituted an ample inquiry and satisfied himself as to the wisdom of the course with which he is credited.

Infectious Diseases Bill.

In the House of Lords on the 10th inst. Lord Thring moved the second reading of this Bill. He said isolation in cases of infectious diseases was impossible in the majority of cases amongst the poor. Hospitals, therefore, were absolutely necessary, and they should be maintained at the public expense. Under this Bill which would not extend to Scotland, Ireland, or the County of London every county council must, under certain conditions, provide an infectious diseases hospital.—Lord Monkswell said the Local Government Board were thoroughly in accord with the object sought to be attained by the Bill—viz. the provision of increased accommodation for the isolation of infectious disease. The formation of hospital districts would be facilitated by the proposals set forth in the Bill which was then read a second time.

Prohibitory Liquor Laws.

On the 13th inst. the Earl of Wemyss asked if Her Majesty's Government would take steps to obtain information regarding the present working of the liquor laws in Canada and the United States in continuation of papers already presented to Parliament.—The Earl of Rosebery said the Secretary for the Colonies had authorized him to say that the request should be attended to.

The Tottenham Fever Hospital.

On the 9th inst. Mr. Howard asked the Parliamentary Secretary to the Local Government Board whether he could say if any and what decision had been come to by the Board with reference to the application of the Metropolitan Asylums Board to extend the time for the reception of patients in the temporary fever hospital at St. Ann's-road, Tottenham.—Mr. Fowler, President of the Board, replied that he had given in instructions to hold a public inquiry with reference to the proposal of the Managers of the metropolitan asylum district that the land in question should be permanently appropriated as a site for a fever hospital.

The Opium Traffic.

On this subject a question was put in the House of Commons by Sir M. Stewart as to whether it was the intention of the Government to bring in a Bill to regulate the traffic in opium.—Mr. Chiststone said though no doubt a strong sentiment existed in the minds of an important section of the public on the matter he was unable to hold out a promise of legislation upon it during the present session. A question was also put by General Goldsborough on the subject which elicited from Sir E. Grey (speaking on behalf of Mr. G. Russell) a reply similar to the above with the additional statement that the Ministry did not intend to request the Government of India to place the sale of opium in that country under the restrictions which apply to the sale of the drug at home.

Tuberculosis.

Mr. William Whitelaw asked the President of the Local Government Board how many carcasses of home bred cattle were condemned on account of tuberculosis during last year.—Mr. Fowler said he had no information as to the number of carcasses of cattle which were condemned by justices on account of tuberculosis during last year.

Sweating.

Colonel Howard Vincent has given notice of a motion favouring the House of Commons to express the opinion that it is the duty of the Government in all Government contracts to make provision against the

evils of sweating and to make every effort to secure the payment of such wages as are generally accepted as current in each trade for competent workmen.

Myopia in School Children.

On the 10th inst. Mr R Wallace, in reference to a statement which had been made in a newspaper to the effect that short-sightedness in school children is greatly on the increase asked if he would inquire whether there was ground for the belief that the conditions of school life were favourable to such increase.—Mr Acland said the Education Department was doing its best to remove some of the alleged causes of the above named defect. Amongst such causes might be mentioned insufficient ventilation and lighting and the use of badly printed books. Inquiries had also been addressed to some of the largest school boards with regard to the effects on the progress of tuition of unwholesome and insufficient food. He proposed to make further inquiry into the question of defective vision in schools.

Regent's Canal Dock.

Mr S. Wallace asked if the attention of the President of the Local Government Board had been drawn to the insanitary condition of the Regent's Canal Dock.—Mr H Fowler replied in the affirmative and had no doubt that proceedings would be taken to abate any nuisance which on investigation shall have been found to be palpable and remediable.

The Case of Surgeon Major Briggs.

On the 11th inst. Mr Lockwood, on the motion to go into Committee of Supply on the Army Estimates called attention to the case of Surgeon Major Briggs, and moved for a select committee to inquire into the refusal to reinstate that officer. The hon. gentleman went fully into the case the particulars of which have already been published and need not here be repeated. The great obstacle to the reinstatement of Mr Briggs was, in view of the military authorities, the publication of a letter in the public press in which he brought certain charges against his superior officer and which letter he declined to withdraw.—Mr Campbell Bannerman recounted the circumstances of the case and explained the reasons why the military authorities had acted as they had done.—Dr Farquharson whilst admitting that Mr Briggs was not free from blame in the matter, thought he had had rather hard measure served out to him.—Mr Lockwood expressed great satisfaction at the remarks of the Secretary of War, and stated on behalf of Mr Briggs that that gentleman was willing to express regret for the letter, and had asked leave to withdraw it.—Mr Campbell Bannerman then said he was gratified to receive that announcement and that he was quite ready to say that that would be done which on the same terms and conditions would have been done in July or August last—viz., the reinstatement of Mr Briggs.

Foot-and-Mouth Disease.

In reply to a question put by Mr Brookfield Mr Gardner said he had received a memorial from the Rye Cattle Market Company asking for a renewal of their licence to hold their usual fortnightly market. The measures taken to cope with the outbreak of foot and mouth disease at Guestling would he hoped prove effectual, and in that case it would be possible very soon to relax the existing restrictions.

Patent Medicines.

On the 13th inst. Mr Frye asked the Home Secretary what was proposed to be done with the penalties imposed upon persons convicted of selling patent medicines containing poisons and whether the Government were prepared to bring in a Bill to amend the Pharmacy Act of 1868 so as to include stamped proprietary medicines.—Mr Asquith said 'patent medicines' containing scheduled poisons were not exempt from the provisions of the Pharmacy Act, 1868, which provides that penalties shall be recovered by the Registrar of the Pharmaceutical Society. From official communications which had been received it would appear to be undesirable that further facilities should be given for the sale of proprietary medicines. As at present advised he was not prepared to propose legislation on the matter.

Child and Female Labour in India.

On the 14th inst. Sir J Gorst called attention to this subject by a question addressed to Mr G Russell who in reply said that the new Factory Law in India presented to Parliament in 1891 extends the principles of the Berlin Conference to the employment of women and children in factories, and is being enforced throughout British India.

The Employment of Unqualified Practitioners.

In the House of Commons on Thursday Mr Bousfield asked the Secretary of State for the Home Department whether he was aware that large numbers of unqualified persons habitually practised as medical men or apothecaries or assistants thereof in London and other populous places whether the only power of preventing such persons from so practising was vested in the Society of Apothecaries under the Act 55 Geo III c. 194 except in cases where such persons use titles prohibited by 'The Medical Act 1858' s. 40 whether the Society of Apothecaries had ceased to use their powers under their Act for many years, and whether he was prepared to consider the advisability of conferring powers similar to those possessed by the Society of Apothecaries upon the General Medical Council, or whether he could suggest any other method of checking such unqualified practitioners.—Mr Asquith said I am not aware of neither have I the means of ascertaining the extent to which unqualified persons habitually practise as medical men, or apothecaries or assistants thereof in London and other populous places. The only power of preventing such persons from so practising is vested in the Society of Apothecaries and that only so far as practice as an apothecary is concerned. I am informed that the Society of Apothecaries have not ceased to use the powers conferred upon them by their Act. I am not prepared to propose any legislation on the subject.—Mr Bousfield. When did the Society last exercise its powers?—Mr Asquith. I cannot say.

Soldiers' Rations.

Major Rasch asked the Secretary of State for War whether he could state what changes had been introduced into soldiers' messing and rations at Aldershot in order to provide for a proper breakfast, dinner and supper.—Mr Campbell Bannerman replied that the changes were too numerous and minute to be stated in answer to a question but a memorandum and appendices had been prepared and the hon. and gallant member might see them.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET Office directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

BARNES, G., L.R.C.P. Edin., M.R.C.S., has been reappointed Medical Officer of Health for the Chard Urban Sanitary District.
BEVERIDGE, A. T. G., M.B. C.M. Aberd., has been reappointed Medical Officer Aberdeen Dispensary.
BROADHURST, H., M.R.C.S. L.R.C.P. Lond., has been appointed Resident Clinical Assistant to the St Marylebone Infirmary, vice G Thornton, M.D., resigned.
BRODRICK, C. C. L.R.C.P. L.R.O.S., L.M. Edin., has been reappointed Medical Officer of Health for the Tavistock Rural Sanitary District.
COLMAR, P. A., M.R.O.S. L.M.C.P. L.S.A. Lond., has been appointed Honorary Medical Officer to the Leovill District Hospital vice Garland, resigned, and also appointed Honorary Consulting Medical Officer and a Vice President.
DAVIDSON, J. MACKENZIE, M.B. C.M. Aberd., has been reappointed Ophthalmic Surgeon of the Aberdeen Hospital for Sick Children.
DE LESSERT, A. A. L.D.S. R.C.S. Irei., has been reappointed Dental Surgeon of the Aberdeen Hospital for Sick Children.
FROSSARD, E. E., L.R.C.P. Lond. M.R.C.S., has been appointed Medical Officer for the Bishop's Lydeard Sanitary District of the Taunton Union.
GARDEN, R. J., M.D. C.M. Aberd., has been reappointed Surgeon of the Aberdeen Hospital for Sick Children.
GLENNIE, J. A. R., M.B. C.M. Aberd., has been appointed Medical Officer for the employees of the Streets &c Department, under the Aberdeen Town Council.
GOODALL, J. K. L.R.C.P., L.M. L.R.C.S. Edin. has been reappointed Medical Officer of Health for the Whittington Urban Sanitary District.
GORDON JOHN, M.D. C.M. Aberd. has been reappointed Assistant Surgeon of the Aberdeen Hospital for Sick Children.
HIRST, G. S. M.B., Ch. M. Edin., has been appointed Deputy Public Vaccinator and Medical Officer for Bishopwearmouth West.
HOOLEY, ARTHUR, L.R.C.P. Edin., M.R.C.S., has been appointed a District Medical Officer for the Epsom Union.
HOW, A. B. L.R.C.P. Lond., M.R.C.S. has been appointed Medical Officer for the Stradbroke Sanitary District of the Horne Union.
KNOW, J. J. M.B. B.C. Camb., L.R.C.P. Lond. has been appointed Medical Officer for the Molesey Sanitary District of the Kingston Union, vice Skimming, resigned.
LAING, A. W. L.R.C.P. Lond. M.R.C.S. has been appointed Medical Officer for the Seventh Sanitary District of the Tonbridge Union.
LEVACK, J. R., M.B. C.M. Aberd. has been appointed Medical Officer for the employees of the Cleansing &c. Department under the Aberdeen Town Council.
MACGREGOR, A. M.D., C.M. Aberd., has been reappointed Assistant Physician of the Aberdeen Hospital for Sick Children.
MARNOCH, J. M.B. C.M. Aberd. has been appointed Medical Officer for the employees of the Gas Department, under the Aberdeen Town Council.
MURPHY, JAMES M. A. M.D. has been appointed Lecturer on Medical Jurisprudence in the University of Durham College of Medicine at Newcastle-on-Tyne, vice Fredk. Page, appointed Joint Lecturer on Surgery.
MYLES, T. M.B., B.S. Dub., has been appointed Medical Officer for the Ireley Sanitary District of the Wigton Union.
ROSE, GEORGE, M.B. C.M. D.P.H. Aberd. has been reappointed Chloroformist of the Aberdeen Hospital for Sick Children.
SHAW, W. W., M.R.C.S., has been appointed Medical Officer of the Workhouse of the Fylde Union.
STANSFIELD, T. E. K. M.B. C.M. Edin. has been appointed Senior Assistant Medical Officer to the London County Council's new Asylum at Claybury, Woodford Essex.
STEPHENSON, W. M.D. F.R.C.S. Edin. has been appointed Physician of the Aberdeen Hospital for Sick Children.
YEARLES, P. MACLEOD, M.R.O.S. L.R.C.P. Lond. has been appointed Honorary Surgeon to the Farringdon General Dispensary.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BOLTON INFIRMARY AND DISPENSARY.—Senior House Surgeon. Salary £120 per annum, with furnished apartments board and attendance.
BLACKBURN AND EAST LANCASHIRE INFIRMARY.—Junior House Surgeon. Salary £60 per annum, with board, lodging, washing &c.

SUNDERLAND INFIRMARY.—Honorary Surgeon.

UNIVERSITY COLLEGE, BRISTOL, MEDICAL SCHOOL.—Medical Tutor. Stipend £125 per annum.

VICTORIA HOSPITAL FOR SICK CHILDREN Hull.—Resident Medical Officer. Salary £50 a year with board, rooms and washing.

WORCESTER GENERAL INFIRMARY.—House Surgeon for three years. Salary £100 per annum with board and residence.

WREKHAM INFIRMARY AND DISPENSARY.—House Surgeon. Salary £85 per annum, with furnished rooms board gas, coal and attendance.

Births, Marriages and Deaths.

BIRTHS.

LIVERMORE.—On March 7th at Holmwood, Stapleton hall road, the wife of William Livermore M.R.C.S. and L.R.C.P. of a son.

MASON.—On March 8th at Oakwood Walton-on-Thames the wife of Arthur H. Mason, M.R.C.S. L.R.C.P. Lond. of a son.

ROWELL.—On March 8th at East Rudham Norfolk the wife of Herbert Ellis Rowell, L.R.C.P. Lond. M.R.C.S. Eng. of a son.

SANDERS.—On March 13th, at Edinburgh the wife of Gordon Sanders M.B. M.R.C.P. Edin. of a daughter.

SHORE.—On March 11th, at St. Bartholomew's Hospital the wife of T. W. Shore M.D. of a daughter.

MARRIAGE.

STALKARTT-FURNES.—On March 1st at St. Mary's Willesden Surgeon Captain Charles Edward Grey Stalkartt, son of the late John Stalkartt, of Seetulpore Chaprath to Margaret Joanna, second daughter of G. Furnes of Roundwood House and Croft Longstone.

DEATHS.

BROTHERTON.—On March 11th at Sydney House Yerbury road, Holloway. Mary Ann, the beloved wife of the late William Henry Brotherton, Surgeon, of Graham House Cambridge road, E. aged 59.

GOSFORD.—On March 12th at 107 Arundel Avenue Liverpool S. William Austin Gosford, L.R.C.P. & S. Edin. L.F.P.S. Glasg. aged 41.

THOMAS.—On Jan. 25th at Blackwood Adelaide S. Australia, John Davies Thomas, M.D. Lond., F.R.C.S. Eng. aged 43 years.

WIGON.—On the 25th ult. at St. Margaret's Bay, near Dover Thomas Carter Wigg M.D. in his 71th year.

Medical Diary for the ensuing Week.

Monday, March 20.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M., Fridays and Saturdays, at the same hour.

ST. BARTHOLOMEW'S HOSPITAL.—Operations 1.30 P.M., and on Tuesday, Wednesday, Friday, and Saturday at the same hour.

ST. MARK'S HOSPITAL.—Operations 2 P.M. Tuesday 2.30 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 2.30 P.M. Friday 2 P.M.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, daily at 10 A.M.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2 P.M. Thursday 2 P.M.

HOSPITAL FOR WOMEN SOHO-SQUARE.—Operations, 2 P.M. and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.

UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M., Thursday 9 A.M. Eye Department 2 P.M.

THROAT HOSPITAL (Golden sq.).—5 P.M. Dr. Greville MacDonald Empyema of Antrum.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. G. H. Savage Symptoms of Mental Dissolution.—Dr. F. Warner Constitutional Differences between Boys and Girls and their Relation to Educational Requirements.

Tuesday, March 21.

GUY'S HOSPITAL.—Operations 1.30 P.M. and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations 2 P.M., Saturday, 2 P.M.

WESTMINSTER HOSPITAL.—Operations 2 P.M.

WEST LONDON HOSPITAL.—Operations 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Skin Department, 1.45 Saturday 9.15.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations Monday 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electro-therapeutics same day 2 P.M.

ROYAL INSTITUTION.—3 P.M. Prof. V. Horsley The Brain.

ROYAL COLLEGE OF PHYSICIANS.—5 P.M. Dr. C. Theodore Williams. Aero-therapeutics in Lung Diseases. (Lumleian Lecture.)

PATHOLOGICAL SOCIETY OF LONDON.—Mr. G. Stoker A Nasal Growth. Dr. E. Klein The Anti-choleraic Vaccination, an Experimental Critique. Card Specimens.—Mr. C. Slater (for Dr. Beaven Bake) The Organs of a Guinea pig inoculated from the Lungs of Lepers. Dr. Lee Dickinson (1) Stenosis of the L-trachea caused by dilatation of the Left Auricle (2) Aortic Aneurysm bursting into the Left Bronchus, (3) Simple Gastric Ulcer unusually situated.

Wednesday, March 22.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1.30 P.M., Saturdays, 2 P.M. Obstetrical Operations Thursdays 2 P.M.

CHARING-CROSS HOSPITAL.—Operations, 3 P.M., and on Thursday and Friday at the same hour.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M. Saturday same hour.

LONDON HOSPITAL.—Operations 2 P.M., Thursday and Saturday, same hour.

ST. PETER'S HOSPITAL, COVENT-GARDEN.—Operations 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations 1.30 P.M. Dental Department, 9.30 A.M. Eye Department, 2 P.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M. and on Saturday.

CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M. Surgical Visits on Wednesday and Saturday at 9.15 A.M.

THROAT HOSPITAL (Golden sq.).—5 P.M. Mr. F. G. Harvey Mastoid Operations.

HUNTERIAN SOCIETY.—8.30 P.M. Dr. G. Newton Pitt The Value of Venesection in the Treatment of Thoracic Aneurysm.—Mr. F. R. Humphreys Two cases of Cheyne-Stokes Respiration, with recovery. Dr. F. Charleswood Turner A case of Intestinal Obstruction.

Thursday, March 23.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations Friday 1.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M. Ear and Throat Department, 9 A.M. Eye Department, 2 P.M.

ROYAL COLLEGE OF PHYSICIANS.—5 P.M. Dr. C. Theodore Williams. Aero-therapeutics in Lung Diseases. (Lumleian Lecture.)

NEUROLOGICAL SOCIETY OF LONDON (20, Hanover-square).—8.30 P.M. Adjourned Discussion on the papers of Dr. Head and Dr. Sherrington.

Friday March 24.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations 2 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Eye Department, 2 P.M.

LONDON SKIN HOSPITAL (40 Fitzroy sq. W.).—3 P.M. Dr. Sanctuary Eczema, its Treatment in connexion with other Diseases and General Review (Post-graduate Lecture.)

CANCER HOSPITAL (Fulham road S.W.).—4 P.M. Mr. W. H. Elam Epithelioma of the Jaw.

CLINICAL SOCIETY OF LONDON.—Living Specimens 4 P.M. Papers at 9 P.M.—Dr. Hale White Two exceptional cases of Peripheral Neuritis one Septicæmic, the other due to Lead Poisoning and presenting Unilateral Facial Paralysis and other rare symptoms.—Mr. A. W. Mayo Robson Infusion (or Transfusion) of Normal Saline Solution in Severe Shock.—Mr. H. Allingham A case of Gastro-enterostomy for Cancer of the Pyloric end of the Stomach.

Saturday, March 25.

UNIVERSITY COLLEGE HOSPITAL.—Operations 2 P.M., and Skin Department, 9.15 A.M.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Publisher."

We cannot undertake to return MSS. not used.

PUBLISHER'S NOTICE

In order to facilitate the work of reference to the volumes of THE LANCET, we have arranged in the future to publish duplicate copies of the Index to each half yearly volume in a form in which they may be subsequently filed or bound together.

We have had a large number of duplicate copies of the Index to the last half-yearly volume printed, and those of our subscribers who may wish to be supplied with loose copies can obtain the same (without extra charge) on making application to the Publisher of THE LANCET.

THE DAILY LIFE OF LEO XIII.

PLAIN living and high thinking" is an ideal life to which few attain in so exemplary a fashion as the present Pontiff. The second factor of this ideal—the "high thinking"—we need not enlarge upon, open as it is to the appreciation of all who have read the Encyclicals on burning questions of the day addressed by the Holy Father to those whom they concern. But the "plain living" he imposes on himself is not so well known, and, now that some of its details have been supplied us, it merits a little notice at our hands. Leo XIII., for all his eighty-two winters, is an early riser, rising at 6 A.M. His simple toilet completed, he proceeds at once to his private chapel, where he says Mass. He then divests himself of his sacred habiliments and in turn listens to the Mass as solemnised by one of his canons. At 8 A.M. he breakfasts the meal consisting of the yolks of two fresh laid eggs beaten up or of a large cup of *café-au-lait*. At noon he dines and this again is a very plain repast—a bowl of soup, a small beefsteak, and a little fruit with half a tumbler of Bordeaux and nothing more. By immemorial custom the Pope does not dine at the same table with others. His dining room is on the first floor, the kitchen immediately underneath, and from this there is access by a spiral staircase. The clerk of the kitchen conveys each dish into the ante-room and there consigns it to the under butler, who in turn carries it into the dining room, where it is served by the chief butler. At the right of the table stands the "scalco" (steward), ready to minister to all his master's wants, whilst there is also a cup bearer

(*pincerna*), but only on special occasions. The table (quadrangular and capable of comfortably accommodating four persons) is covered with a rich cloth of red damask, over which is spread a coverlet of the finest linen embroidered by the nuns. On rising from dinner the Pope leaves the armchair (*seggiolone*) for the sofa, which stands at another part of the spacious room, and on this he takes an hour's siesta. The remainder of the afternoon and evening is divided between business and study till the hour arrives for "cena" (supper), another meal of the simplest kind, consisting generally of an egg and a little salad. By 10 P.M. His Holiness has retired. A scudo (5 fr. 80c.—less than five shillings) covers the daily cost of his eating and drinking—very different from the sums lavished on the "pontifical cena" of not a few of his predecessors. Pius IX.'s bills were considerably greater than Leo XIII.'s, about thirty scudi a day. But then, Pius was an invalid, whose dietary necessitated more expensive food and costlier wines, and all that he did not consume became the perquisites of his attendants. However Leo says "Sono solo e la spesa deve essere fatta per un solo" (I am alone, and the expense should be made for one only) and he finds the simple fare he allows himself compatible with the full and effective discharge of all his duties as Head of the Catholic Church, and with it the daily prosecution of studies that have placed him high on the roll of theologians and men of letters. The same rule of life (so far as eating and drinking are concerned) was shared by the First Napoleon, who always maintained that men habitually ate and drank too much, and whose habit it was to rise from table with the feeling that he could still take as much as he had already consumed. And yet he was all his life a stout man and got through an amount of mental and bodily work daily which would have exhausted the energies of half a dozen of his more self-indulgent staff.

Mr D. D. Dixon is thanked for his communication.

THE REMUNERATION OF MEDICAL PRACTITIONERS

To the Editors of THE LANCET

SIRS—Such statements as those of Mr Gladstone which you comment on, and of Mr Goschen about "sombre consulting rooms" are doing us (the general practitioners of the United Kingdom) a lot of harm. The general idea seems to be that we may be sponged on with impunity. I have recently had four casualty cases in succession, which have gone away without paying a farthing and none of whom have I seen or heard of since. The last one indeed, was brought by a man who said he thought he would act the Samaritan and would himself pay if the patient did not. Of course the patient did not, and the Samaritan relied on the fact that I should see his face no more. Neither the one nor the other have I seen since. It would be a great advantage if one could get statistics of the average income of medical men. One of the journals might undertake this, for, though medical men are shy individually of letting their incomes be known, there is no reason why they should not communicate them anonymously on a post-card to some one authorised to receive and collate them. My opinion is that, of general practitioners it is quite a minority who are paying their way out of professional income. But this sort of thing cannot last for ever and with the numerous assaults which are being made on private property one may confidently predict that the end is within measurable distance. And when the end comes whom will the British public have to look after their ailments? But that is their affair not mine.

I am, Sirs, yours faithfully,

March 4th, 1893.

A SUBURBAN PRACTITIONER.

"POST-SCARLATINAL DIPHTHERIA."

To the Editors of THE LANCET

SIRS,—Will you allow me to correct an error in your report of the discussion which followed upon a paper on Post-scarlatinal Diphtheria recently read by Mr E. D. R. Sweeting before the Epidemiological Society? I am credited with holding the opinion that site and surroundings are the most efficient factors and with adducing the experience of this hospital in support of this opinion whereas I attempted to show that post-scarlatinal diphtheria was mainly the outcome of overcrowding and that the differences in the incidence of the disease were correlated to differences in the amount of cubic space allowed to patients—that is, to the degree of overcrowding.

I am, Sirs, yours faithfully,

C. E. MATTHEWS, M.D.

Gore Farm Hospital, Dartford, March 14th, 1893.

ANTIQUITY OF THE TITLE OF SURGEON MAJOR.

To the Editors of THE LANCET

SIRS,—In THE LANCET of 1894 vol. i. page 232, it is stated that the term "Surgeon Major" is as old as the "time of Ambrose Pare" who died in 1590. I shall be greatly obliged if you can give me any verification of the fact, as it would be very interesting.

I am, Sirs, yours faithfully

J. P. H. BOILEAU,

Meerut, Bengal, Feb 11th, 1893. Brigade-Surgeon Lieut. Col., A.M.S.

* Our correspondent might be able to obtain the information he requires from Surgeon Colonel Gore, Army Medical Staff.—Ed. L.

A. E. ALDRIDGE

During the week marked copies of the following newspapers have been received — Thompson's Kansas Journal, City Press & Interior Journal, Birmingham Daily Post & Gazette, Kentucky Times Courier Gazette, Manchester Guardian, Isle of Wight County Press, Barbary Guardian, Saturday Journal, Sunday Times, Border County Gazette, Land and Water Worker, Daily News, Edinburgh Evening Dispatch, The Freeman, London Freeman's Journal, St. James, Dundee Courier Free Press, Glasgow Chronicle, Times of India, Pioneer Mail, Weekly Free Press and Aberdeen Herald, Reading Mercury, Lincoln Journal, Northampton Mercury, Local Government Chronicle, Waikato Standard, Long Bay Post, Little Western Yorkshire Post, Daily Morning, Le Courrier de la Presse (Paris), Guy's Hospital Gazette, Liverpool Echo, Weekly News (Cork), The Age (Melbourne), Surrey Advertiser, West Essex Advertiser, Carmel Petitioner, Worcester Chronicle, North English Advertiser, Dorset Weekly Sun, West Wales Journal, Ennisville Gazette, Gloucestershire Times, Grosvenor Advertiser, Llanidloes Democrat, Fife & Perth Advertiser, Guardian, Post-Opinion, Redfern Times.

Meerut Bengal, Feb 11th, 1893. Brigade-Surgeon Lieut. Col., A.M.S.

* Our correspondent might be able to obtain the information he requires from Surgeon Colonel Gore, Army Medical Staff.—ED. L.

REPORT OF THE LANCET COMMISSION

APPOINTED TO INVESTIGATE THE SUBJECT OF THE

ADMINISTRATION OF CHLOROFORM

AND OTHER ANÆSTHETICS

FROM A CLINICAL STANDPOINT

It will be remembered that we, as the Editors of THE LANCET, appointed Dr. Lauder Branton as our representative on the Second Hyderabad Chloroform Commission which was formed to investigate the action of chloroform on the human organism so far as that could be ascertained by experimentation on living animals. We thought that it would be well to supplement the work of that Commission as far as possible by a consideration of the results arrived at by clinical observation. Our investigation into the relative safety of anæsthetics as usually administered to human beings was therefore commenced as soon as the Second Hyderabad Commission's report was received. The task, however, was found to be beset with so many difficulties and inherent delays that we were prevented from publishing the report until the present time. Such a mass of material reached us and the work of arranging and collating it has been of such an exacting and laborious nature that we have been compelled to delay the publication much longer than we had originally intended.

We wish to express our indebtedness to Dr. Dudley Buxton for undertaking the direction of the inquiry as our Commissioner, and for placing at our service the results of his large clinical experience and knowledge of the scientific bearings of the subject. It should, however, be distinctly understood that the report is purely a scientific record of facts which our Commissioner has studiously endeavoured to present without bias and without any reference to his own views on matters which are the subject of controversy.

METHODS OF COLLECTING INFORMATION

Referring to the sources whence the statistics, which we desire to bring under the notice of our readers, have been obtained, it will be remembered in the first place that we issued to the members of the profession a form, and asked the recipients to fill in particulars of their experience as regards anæsthetics.

The form desired information on the following points—
 (1) What anæsthetic do you usually employ, and how? (Apparatus?) Average number of times a year? Do you keep an accurate register? What class of cases (operation, midwifery &c.)? Can you give particulars of any deaths? Agents used? Apparatus? Nature of operation? Age sex and peculiarities of patient? Posture? How long under? Did heart or respiration stop first? If a post-mortem, particulars? Can you give particulars of any dangerous cases and means used for resuscitation? Please give particulars as above.
 Signed () Address () Qualifications and school ()

A form of larger size was in addition sent with a like request to each hospital of the United Kingdom containing more than ten beds. Further, this form, accompanied by a circular letter couched in the language of the country to which it was sent, was despatched to all the larger hospitals of the Continent as well as to India, America and the Colonies.

This form asked for information in the following way—
 Name of institution. Approximate number of times anæsthetics have been given during the past ten (1) years. Chloroform used and for what cases. Relative frequency (a) Ether and for what cases, (b) mixtures (name) and for what cases. Other anæsthetics. Deaths under anæsthetic, how many and under what anæsthetic. Particulars of death, sex, age of patient, operation, how much anæsthetic used, duration of administration &c., by whom given. Other par-

ticulars as to experience of institution as to relative dangers of anæsthetics (1) At operation, (2) after operation, and facts bearing on this question.

As, however, the records received in reply to these circulars for the most part bore reference to recent cases, these sources of information were supplemented by a careful search for particulars concerning dangerous and fatal cases under anæsthetics reported in the current professional and lay papers. The reports thus obtained were thoroughly sifted by collation of the various accounts, and, when possible, by reference to the reports tendered to us by medical men. As to the value of such narratives being lessened for want of the personal guarantee of accuracy of the details by the administrator, it should be borne in mind that in by far the largest number of cases the particulars were usually given on oath before a coroner's court, and, further, at any rate in the case of medical journals, were conveyed to the press not through newspaper clippings, but directly from the responsible administrator or surgeon. When this was not the case particulars were usually asked for and, when possible, obtained from the medical man interested in the case.

In order to arrive at a continuous series of cases from 1847 (the date of the first employment of chloroform as an anæsthetic) not only were the above sources of information used, but the records of Snow—a most valuable and carefully kept sequence—and those collected by the committee of the Royal Medical and Chirurgical Society, published in their Transactions in 1884 (vol. xlvii.), were laid under contribution and again collated with the records derived from the other sources.

The authorities of some of the large hospitals very courteously permitted our Commissioner to inspect their case-books and to extract cases from them which had not appeared in the circulated forms or in any published works. Further information was in this way also obtained concerning cases already recorded. The records supplied by the Registrar-General of Deaths further gave additional information of casualties under anæsthetics. It seems from reference to these tables that more deaths from anæsthetics are recorded by the Registrar-General than are to be found in any other published records or in the private records kept by some of the hospitals.

As regards Scotland, the present condition of the law as to inquiries into the circumstances of deaths under anæsthetics greatly interferes with accurate information being obtained upon this matter.

CLASSIFICATION OF CASES

In arranging the report we have found it necessary to deal with chloroform, ether, mixtures of anæsthetics, the less common forms of anæsthetics such as bromide of ethyl and nitrous oxide. The reports of cases have been divided into the following classes: (1) Deaths under and apparently due to an anæsthetic, (2) deaths under and remotely due to an anæsthetic, and (3) untoward cases—i.e., cases in which some mishap occurred which was not followed by fatal results, but which was directly or remotely due to the anæsthetics employed. To illustrate our meaning we may cite some illustrative cases.

1. A patient, after inhaling chloroform for five minutes and just before the beginning of the operation, suddenly turns pale, his respiration stops and in spite of all restorative measures he dies. Here, if the patient is completely under the anæsthetic, and if other causes of asphyxia are absent the death may fairly be ascribed as due to the anæsthetic, and would be classed in the first category.

2. If a patient passes through the narcosis and operation

SUBSCRIPTION

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year £12 6 | Six Months £0 18 8

TO THE CONTINENT, COLONIES, UNITED

STATES, INDIA, CHINA, AND ALL PLACES

ABROAD One Year 1 14 8

*. In consequence of the new postal arrangements, the Annual Subscription for India, China, and all foreign countries will now be reduced to £1 14s 8d, instead of £1 16s 10d. as formerly

Post Office Orders and Cheques should be addressed to The Publisher, THE LANCET Office, 423, Strand, London, and crossed "London and Westminster Bank, St. James's-square"

An original and novel feature of 'THE LANCET General Advertiser' is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agents for the Advertisement Department in France—J. ASTIER, 65, Rue Caumartin, Paris.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to initials only

The cases recorded have not only occurred in hospitals, but the record takes account also of cases occurring in private practice. In attempting to deduce any conclusions from the tables from which the above list of localities from which deaths were reported has been compiled, the same difficulties have arisen as were mentioned in dealing with the subject of the influence of age and sex on mortality under chloroform. The extent of population, hospital accommodation, and the proportion of medical men and their facilities for operations enter largely into statistics of this kind as disturbing factors. Again, it must be assumed that the records of fatalities or dangerous cases would be more accurately kept and be more accessible in the larger European or American towns than, for example, in African or small outlying Canadian towns. The readiness with which chloroform is given in a London hospital is in marked contrast to what obtains in smaller towns, even in England, and still more so in remote towns elsewhere. Another disturbing factor is the unwillingness of some persons to record fatalities under chloroform. We have above also noticed the fact that in Scotland, where chloroform is so widely and extensively employed, few reliable sources of information exist of the deaths which result from its exhibition. It has, however, been thought advisable to introduce into the Report the above list of places as well as other tables and lists in the hope that they may afford a guide for further investigations both in the way of directing attention to statistics desirable, but at present inaccessible, and in discouraging a loss of time over equivocal arguments based upon unsatisfactory and fallacious premises.

In further reference to race and the influence of climate it must be admitted that there are no materials upon which to base any conclusive arguments. The only satisfactory way to deal with this question would be to compare—not 50,000 cases occurring in the practice of one surgeon in one climate with an equivalent number of cases of another surgeon in a country sufficiently remote to ensure differences of race, mode of life, of temperature and environment, but a sufficiently large number of cases in different countries occurring in the practice of a sufficient number of persons to eliminate individual failings or extra care in the administration of the anæsthetic. It would, for example, be valueless to institute a comparison between the individual practices of two surgeons, one of whom operated almost solely on cases of minor surgery, whilst the other was constantly called upon to deal with the graver and more prolonged procedures of surgery as called for in large and populous towns, especially those in which machinery accidents are rife.

METHODS EMPLOYED FOR ADMINISTERING CHLOROFORM

One point which appeared to our Commissioner to be of manifest importance in the inquiry was whether any relation could be shown to exist between particular methods of giving chloroform and accidents under its use. If, for example, one method could be shown to be frequently accompanied by such accidents, such occurrences might be taken as indicative of a possible fault in the method. On the other hand, it was recognised that the problem was complicated by the fact that, the methods not being employed with equal frequency those most generally in use might, by showing more deaths or accidents, appear—and of course fallaciously—to be the more unsafe. It was necessary to guard against this form of error and to make allowance for it. The sequel appears to show that the method employed has really little influence in determining the result. The cases were divided into

1. *Those in which no special form of inhaler was employed*—Under this heading the following modes of administration were specified

Chloroform poured on a handkerchief

- “ ” ” lint.
- “ ” ” a towel.
- “ ” ” a napkin.
- “ ” ” into an extemporised cone.
- “ ” ” a sponge.

In fewer instances the process is described as having been conducted by the “open method,” or chloroform given from a “coil of paper,” “cloths,” “compress,” and so on. The recorded deaths resulting from chloroform being administered without an inhaler are rather more than double those occurring when an inhaler is used, but from inquiries made at various hospitals and in private practice there is no doubt that the

exhibition of chloroform without the use of an inhaler is much more frequent than is the employment of a distinct mechanical contrivance such as Clover's or Junker's apparatus

2. *Deaths under chloroform when a specified apparatus (inhaler) is employed*—In the order of the frequency of deaths during their use, the following inhalers are specified

“Inhaler” (kind unspecified)	Clover's inhaler
Skinner's inhaler (a simple flannel mask stretched on a wire frame)	Bismarck's „
Snow's inhaler	Metal cone.
Junker's „	Guy's Hospital inhaler
	Morton's ether inhaler
	Weiss's apparatus

We have, however, no figures to show the number of times these inhalers are used, and, in the absence of these, there is no accurate basis for comparison in regard to their safety or danger. It appears that in some instances chloroform has, with fatal results, been given from an ether inhaler. The frequency of use of the above inhalers must be taken into account. Skinner's apparatus, from its simplicity and portability, is probably used very much more frequently than any other. Snow's and Clover's inhalers are seldom, if ever, employed at the present time. Skinner's, Junker's (in one of its several modifications) or some form of cone, containing a sponge or piece of lint, probably represent the inhalers at present in vogue in the order of their frequency of employment.

It is a remarkable fact that, in more than half the cases of fatalities reported to us, no mention is made of the method which was followed in giving the chloroform, and even when the apparatus or method is named no particulars are furnished indicating the manner in which the anæsthetic was exhibited. That such details are essential the following example will indicate. Case A “Open method”, chloroform “poured” on lint “after the manner of Syme,” who taught that plenty of the drug should be used. Case B “Open method”, chloroform “dropped” on lint after the manner advocated by the dosimetric school, who teach that by dropping chloroform literally *guttatim* on lint the utmost safety is ensured. Here two methods diametrically opposed in principle are described by the same phrase, “open method.” Each of these schools would hold the other responsible for the faulty character of their method for any mishap occurring during the chloroformisation.

CAUSES ASSIGNED FOR DEATH

In giving the causes which are stated to have occasioned death, care has been taken to present if not the exact words at least the exact sense of the words employed by the narrators of the cases. This has been done to avoid any bias which might unconsciously attribute results following upon well defined symptoms. A careful examination of the cases, both in the following abstracts and more especially in the cases given at length will show that in most instances the causes assigned are very complex and no very definite single cause is advanced by itself. In some few cases the causes alleged do not appear to correspond with the symptoms given, but even here strict attention has been given to the narrator's views, whilst attention is at the same time drawn to the discrepancy and an explanation offered. In drawing up this summary the greatest difficulty has arisen in many cases from the looseness and inadequacy of the published records. It has been necessary in some instances to place apparently similar cases under different headings when the causes assigned for death have been different, although the lesions have been similar. Thus, in one case death is attributed by the narrator to syncope, although it is stated that food was found in the *œnæpipe* which, it may be presumed, caused respiratory trouble, leading it may be, to syncope as an ultimate result. In drawing up the abstracts from the reports of cases these sources of error have been eliminated, as far as possible, by assigning the evident and immediate cause of death and not the remote one. In the case alluded to above no one would accept “syncope” as the true cause of death, except in the sense that dissolution must always be eventually associated with cessation of the heart's action. Of predisposing causes “Intemperance” and wasting diseases the existence of emphysema, pathological conditions of the heart and bloodvessels are those most noted. They really appear under two distinct headings. Intemperance may be noticed here, but the other conditions will be fully described later under the accounts of the necropsies held on persons dying under chloroform.

satisfactorily, but dies within a few hours from some cause, such as vomiting or bronchial irritation, the death is some times put down to the anæsthetic, but as such a cause could only act remotely it is classed in the report under the category of "remote deaths." The same remark applies to cases of renal trouble occurring some time subsequently to the use of ether.

3 If, while under an anæsthetic, the patient suddenly becomes faint or asphyxiated, and the condition be due directly or indirectly to the anæsthetic, the case is put into the category of "untoward cases," always provided the patient recovers. If other causes are at work besides the anæsthetic the case would be classed as "untoward case, remotely due to the anæsthetic."

The statistics as regards these cases have been so arranged as to reveal any similarities or differences occurring in private practice and hospital practice. Points of especial interest in the inquiry will be found to be the determination of the question of how far age and sex are factors in determining fatalities under anæsthetics. Another question of interest is the geographical distribution of these fatalities. Can the influence of race, climate and the conditions of life determined by these have anything to do with these fatalities? We have also dealt with the method of administration of the various anæsthetics. Regarding the causes assigned for death under chloroform, these include both *assumed pre disposing* causes for death—e.g., presence of intemperance or exhausting disease, as carcinoma, emphysema &c.—and *determining causes*, such as vomiting during the administration, paralysis of respiration, overdosage, or failure of the heart's action. The phenomena of the anæsthesia are grouped so as to bring out, as far as the records allowed us, the contrast between the respiratory and circulatory systems, statistics being furnished to show whether the heart or the respiration was reported as having failed first.

The fact of the patient having previously been subjected to an anæsthetic is next considered. This is followed by an account of the methods employed to resuscitate the patient. A table follows which gives all the operations during which a death took place as far as records have reached us, an attempt being made to arrange them so as to indicate whether any particular class of operations offers peculiar dangers. The post-mortem examinations when made and recorded are carefully summarised as to fact, no inferences being given.

We next proceed to consider the *nature of the operation*, or surgical procedure carried on at the time of death, and to make an inquiry as to whether the operation had any causal relation with the fatality.

PART I—CHLOROFORM

AGE AND SEX AS DETERMINING FACTORS.

Taking up these questions as they arise, we now proceed to endeavour to discover by means of our carefully collated figures obtained from the sources which we have mentioned whether age and sex have any determining influence on fatal cases under chloroform. We find that no age possesses immunity. Taking periods of five years between birth and the age of seventy five, the extremes reached by the statistics before us, we find the proportion between the sexes to be as follows—

Proportion of Fatalities of Males to Females	
Ages	Proportion Males. Females
1 to 5 years	7 to 2
5 to 10 "	19 to 5
10 to 15 "	15 to 6
15 to 20 "	equal
20 to 25 "	26 to 15
25 to 30 "	22 to 6
30 to 35 "	17 to 8
35 to 40 "	17 to 7
40 to 45 "	34 to 11
45 to 50 "	34 to 9
50 to 55 "	13 to 3
55 to 60 "	24 to 7
60 to 65 "	no females.
65 to 70 "	equal.
70 to 75 "	2 to 1

According to these figures, the greatest number of deaths in males appears to take place between the ages of twenty five and fifty, a period of life when men are most liable to injuries and surgical diseases. The fatalities of women are most frequent between the ages of twenty-one and forty five, a period which includes the epoch of parturition and the age at which operations for carcinoma are most commonly performed.

In drawing any conclusions from the above figures it must be carefully remembered that they only represent the proportion of deaths of males to females under chloroform, as reported to the Commission, and do not represent a proportion of deaths in an equal number of inhalations by males and females. Probably many more males are compelled to take chloroform for the performance of surgical operations arising from accidents than obtains in the case of women. Unfortunately, it is impossible for the Commission to do more than suggest this explanation of a seeming partial immunity for women, as until all cases of inhalation of chloroform are recorded and some thousands of records, including an equal number of the sexes, are compared and classified as above no reliable statistics will be procurable.

GEOGRAPHICAL DISTRIBUTION OF FATALITIES

Deaths are reported from all quarters of the globe, the following places being those from which reports have been received—

AFRICA.	AMERICA.	ASIA.
Mauritius. Egypt (Suez). Whitesea Colony).	(Cape) Hamilton (Ontario) City Toronto. Toronto General Hos Ancaster (Ontario) Dunville (Ontario) St. John's (New Bruns wick) Halifax (Nova Scotia). London (Ontario). New Brunswick. Quebec.	India. Burman. Burmah. Hyderabad. Japan, Yokohama.

 Weakly infant (lungs never properly inflated) 1
 Larynx, spasm of 1

RESPIRATORY TRACT (see also above)
 Lungs paralysis of ("fatty heart") 1
 Lungs tuberculous 1
 Lungs and pleura abscess consolidation 1
 Respiration obstruction to, by pharyngeal growth 1
 Respiratory centre paralysis of 1
 Respiratory muscles, heart dilated, albuminuria 2
 1

SHOCK.

Hæmorrhage 1
 Heart fatty, dilated 1
 Very feeble 1
 Not completely under the influence of the anæsthetic 2
 Leukæmic 1
 Reflex shock 1
 (?) Reflex shock 1
 Stomach, rupture of 1
 Subarachnoid hæmorrhage (see Brain) 1
 Tetanus 1
 Thrombosis of venous system 1
 Vomit entering air passages 2
 Vomiting veins in pia mater and viscera gorged 1
 (?) Valvular disease, heart pale, mitral thickening, aortic atheroma 1
 16

HEART FAILURE AND RESPIRATORY CESSATION

Owing to the grouping of the cause assigned with subsidiary or adjuvant causes of death, the table just given is less clear to a superficial inspection than would have been the case had one leading cause been assigned. To elucidate the point under consideration—viz., the cause of death—a further tabulation is offered which has been arrived at from such figures and statements as we have had at our disposal, in which the relative frequency of the heart failure and respiratory cessation is compared.

Of the 506 records of cases which have come under our notice in this connexion the pulse is stated by the person who reports the death to have failed first in 143 instances, while in 59 records the respiration is described as being primarily stopped, in 46 it is mentioned that the respiration and circulation (as judged by the pulse) ceased simultaneously, whilst in 26 the pulse probably, it is asserted, failed first, in 4 the respiration probably failed first, and in 12 they probably failed simultaneously, in 211 cases no record was given as to which failed first. The word "probably" needs some explanation, lest it should appear that an unscientific nomenclature had been adopted. In many of the records of cases the reporters have expressed their opinion, more or less strongly, that either the pulse or respiration ceased first or simultaneously. In those cases in which no direct and distinct affirmation was offered, we have used the qualifying word "probably," indicating it both in the tables and in the summary by the inserted note of interrogation, thus—(?)

Of the cases collected by the Committee of the Royal Medical and Chirurgical Society, out of 83 cases 26 are given in which the pulse failed first, 4 in which respiration failed first, 11 in which respiration and circulation failed simultaneously, 9 in which the pulse probably failed first, 2 in which the respiration probably failed first and 7 in which they probably failed simultaneously, while 24 cases had no record of these points. These results may be tabulated together with those derived from the records collected from the press, those obtained from private and hospital sources in response to THE LANCET inquiry form, together with those derived from the private statistics of hospitals.

	From the Medical and Chirurgical Reports,	Recorded Cases in Journals	THE LANCET Inquiry Hos. Private pital. practice.		Hospital Cases not included elsewhere	Total
Pulse failed first	26	143	5	2	2	183
Respiration failed first	4	57	7	2	—	73
Pulse and respiration failed simultaneously	11	46	1	—	—	58
Pulse probably failed first	9	20	—	2	7	46
Respiration probably failed first	2	4	—	—	1	7
Probably failed simultaneously	7	12	—	—	—	19
No record obtained	24	211	13	1	4	253

It thus appears that while it is stated that in 183 cases the pulse failed before respiration and in 44 more it probably did so—i.e. in 227 instances—in 73 for certain and probably in 7

PREDISPOSING CAUSES OF DEATH

Intemperance—It has been widely recognised that persons addicted to excesses in alcoholic liquors, take anæsthetics badly and run peculiar risks. In the cases reported in the press we find a definite record of intemperance in twenty-four males and five females and a doubtful record in three males. In the records sent to us from medical men of deaths occurring in private practice under chloroform, we find it existent in the cases of one male, two females, and in the equivalent list from hospital practice in three males, and in the records obtained from the private statistics kept in hospitals we find mention of one male. This gives a total of thirty-eight.

Wasting Diseases—The presence of carcinoma in nine cases is mentioned as having been a possibly predisposing cause of death from the enfeeblement it had engendered.

Emphysema—The existence of this condition, a presumably dangerous factor, is mentioned in twelve cases.

Vomiting—Vomiting during the operation is noted as having occurred eighteen times. There are several points of interest about this statement. First, vomiting shows either loading of the stomach before the administration of the anæsthetic—a procedure about the danger of which there can be no question, both from general shock and from the danger lest the vomit be sucked back into the air passages, and secondly, the probability that an insufficient quantity of the anæsthetic was given, and that the patient consequently suffered from the shock both of the operation and of the chloroform.

IMMEDIATE CAUSES OF DEATH

In the cases collected by the Royal Medical and Chirurgical Society and supplemented by Dr. Snow's records the results are grouped (1) under failure of respiration, (2) causes associated with cardiac failure, and contributing causes are added in brackets. In the following table, when a note of interrogation is added it means that the cases, although probably, as the records seem to show, instances of the particular lesion mentioned, yet, as the account shows, some doubt existed in the mind of the original reporter. Its meaning may be taken as an equivalent to the words "probably from overdose," "probably from syncope" &c, as the case may be. The following table gives the causes assigned for death—

Respiration, failure of	3
" " probably from overdose	3
(?) " " (probably)	20
" " holding breath	1
" " " (?) overdose	2
(?) " " (?) overdose	3
	32
Shock (?) syncope in pre-anæsthetic stage	4

ABSTRACT OF

The Goulstonian Lectures

ON THE

CHEMICAL PHYSIOLOGY OF THE ANIMAL CELL

Delivered at the Royal College of Physicians on Tuesday, March 14th,

By W D HALLIBURTON, M.D.,
FRCP LOND, FRS,

PROFESSOR OF PHYSIOLOGY, KING'S COLLEGE, LONDON

LECTURE III.

THE COAGULATION OF THE BLOOD

[In commencing his last lecture Dr Halliburton expressed his indebtedness to his fellow worker Mr T G Brodie Demonstrator of Physiology at King's College, and referred to the researches of W L Dickinson, E H Hankin, Brücke, Hammarsten, Green, Ringer and Sainsbury, Arthus and Pagès, and proceeded at greater length to criticise the results obtained by Pekelharing as follows.]

The substances which have at various times received the names of fibrinoplastic substance, fibrin ferment, cell globulin β , serum fibrinogen, fibrinogen. A tissue-fibrinogen and so forth are all varieties of one substance, which is a nucleo-albumen, and, further, it is in all cases a nucleo-albumen which in coöperation with calcium compounds brings about coagulation in the blood. The question then arises, Does this definitely, once and for all, settle the long vexed subject of blood coagulation? I am afraid it does not—it helps us a little nearer the truth, but the final solution of the problem may be a long way off yet. The observations which have been made by Mr Brodie and myself were attempts to answer some of the points left undecided by Pekelharing's work, and I wish that it had fallen to my lot to announce that all the difficulties had disappeared, but as we went on what we found was that new and previously unsuspected difficulties made their appearance. I will first point out what I conceive to be the weak links in Pekelharing's chain of evidence.

1. The theory that "peptone" hinders coagulation because of its great affinity for calcium salts is a very tempting hypothesis. It is supported by the fact that injection of a soluble calcium salt counteracts its action. This fact we have confirmed. We used anaesthetised rabbits in our experiments and injected about 10 cc. of 10 per cent. "peptone" solution into the external jugular vein, after about a minute a small quantity of blood was withdrawn from the carotid artery, this took about twenty minutes to coagulate. Then 50 cc. of a 1 per cent solution of calcium chloride was injected, and another sample of blood withdrawn, this clotted in a few seconds. The same result was obtained when "leech extract" was used instead of peptone, leech extract probably owes its activity to a proteose and is much more effective in hindering coagulation in the case of the rabbit than commercial peptone. The analogy of "peptone" and soap, which has already been pointed out also lends support to Pekelharing's views. But I have heard the objection raised that other substances which undoubtedly have a great affinity for calcium do not act in this way and I have been asked whether potassium oxalate acts like peptone. We have put this to the test of experiment and have proved that the injection of a few cubic centimetres of a weak (0.4 per cent) solution of this salt renders the blood when it is subsequently drawn off very slow in coagulating. In one experiment a sample of blood, which was drawn off before the injection, clotted in less than a minute, after this injection another sample did not clot for seventeen minutes. We thus have an additional confirmation of Pekelharing's hypothesis.

2. The second difficulty may be put in the form of a question. Why do not nucleo-albumens cause coagulation to occur in extra vascular as readily as they do in intra vascular plasma? The amount of calcium salts is presumably

the same in both. I have tried a good many experiments with salted plasma, and found, like Pekelharing, that if the nucleo-albumen is previously gently warmed with a little calcium chloride solution it acts like fibrin ferment and causes a rapid formation of fibrin, calcium chloride alone does not produce this result. But if the treatment with calcium chloride is omitted the nucleo-albumen has little or no activity in this direction, it may even hinder the coagulation in comparison with control specimens of the same salted plasma which had been diluted with water. I feel quite unable to offer an adequate explanation of this difficulty.

3. If fibrin ferment behaves as Pekelharing considers its action differs from that of all other ferments with which we are familiar. The usual action of a ferment is to act as a water carrier, and, having given water to the substance on which it acts, splitting into new products takes place (hydrolysis). There is of course no reason why ferments should not act as calcium carriers, but if we include such an action we must either extend the meaning of the term fermentation or abandon the use of the word altogether in speaking of blood coagulation. Of all ferment actions that of rennet in causing milk to curdle is most nearly akin to blood clotting. This resemblance has been a matter of remark from the time of Andrew Buchanan onwards. In each case we have the conversion of a soluble into an insoluble proteid, and in each case the presence of a calcium salt is necessary. Hammarsten showed that the process of milk curdling consists of two distinct stages, and more recently Ringer has confirmed this observation. It appears to me quite probable that in fibrin formation there is a similar double process, the action of the calcium coming in at the end in causing the separation of the clot. But it is very difficult to prove or disprove this idea. As for milk it is possible to boil it without coagulating the proteid, and one can thus destroy the ferment. With blood plasma this is impossible, for the blood proteids are coagulated by heat and so one would destroy both ferment and fermentable substance. I shall, however, not pretend to be able to decide this question, sufficient data have not yet accumulated for a definite opinion to be pronounced one way or the other, and, therefore, I shall for the present retain the use of the conventional term "fibrin ferment."

4. The last difficulty standing in the way of our full acceptance of Pekelharing's theories is that it takes no cognisance of the part that carbonic acid plays in blood coagulation. Clinical evidence supports physiological experiments in that it is the venous blood which is most liable to be coagulated. We can hardly doubt from such evidence that either the quantity or more probably the tension of carbonic acid has an important influence in hindering or promoting coagulation. I must again confess myself unable to see the full bearing of such facts, and I also think that in the present state of our knowledge it would not be safe to attempt any theorising as to the way in which they are to be fitted into Pekelharing's hypothesis.

I may now pass to a more systematic account of the experiments which Mr Brodie and I have been making during the last two years, they are very numerous, and all I shall attempt is a summary of their chief results. They were commenced with the object of determining whether the nucleo-albumens obtained by the sodium chloride method had the same physiological action as the nucleo-albumens obtained by Wooldridge's acetic acid method and termed by him "tissue fibrinogens." The fact that both produce intra vascular coagulation formed part of the chain of evidence that the two materials were practically the same, upon which I dwelt in my second lecture. The next point taken up was whether the leucithin, which I regard as an impurity, but to which Wooldridge attached considerable importance, was really the active substance, or whether the nucleo-albumen itself produces the result.

Having shown by experiment that that substance produces its effect *in vivo* its leucithin whichever of the two methods is adopted for its preparation, the greater number of our subsequent experiments were performed with the material prepared by the sodium chloride method from the thymus. We adopted this method because it is more rapid and the results obtained were more certain. The material prepared by Wooldridge's method often produces no intra vascular clotting at all, this was recognised by Wooldridge himself and he spoke of it as the "negative phase" in his experiments because in the dog which was the animal he chiefly used the blood was not only free from clot but it clotted with tardiness after removal from the

¹ The term "peptone" includes the proteoses with which it is generally mixed.

LECTURE III

THE COAGULATION OF THE BLOOD

[In commencing his last lecture Dr. Halliburton expressed his indebtedness to his fellow worker Mr. T. G. Brodie. Demonstrator of Physiology at King's College and referred to the researches of W. L. Dickinson, E. H. Hankin, Dr. H. Hammarsten, Green, Ringer and Sansbury Arbuthnot and Paget, and proceeded at greater length to enunciate the results obtained by Pechelharng as follows.]

The substances which have at various times received the names of fibrinoplastic substance, fibrin ferment, cell-globulin, serum fibrinogen, fibrinogen. A tissue-fibrinogen and so forth are all varieties of one substance, which is a nucleo-albumen and, further, it is in all cases a nucleo-albumen which in co-operation with calcium compounds brings about coagulation in the blood. The question then arises, Does this definitely once and for all settle the long vexed subject of blood coagulation? I am afraid it does not. It lays us a little nearer the truth, but the final solution of the problem may be a long way off yet. The observations which have been made by Mr. Brodie and myself were attempts to answer some of the points left undecided by Pechelharng's work, and I wish that it had fallen to my lot to announce that all the difficulties had disappeared, but as we went on what we found was that new and previously unsuspected difficulties made their appearance. I will first point out what I conceive to be the weak links in Pechelharng's chain of evidence.

1. The theory that peptone "hinders" coagulation because of its great affinity for calcium salts is a very tempting hypothesis. It is supported by the fact that injection of a soluble calcium salt counteracts its action. This may have been confirmed. We used neutralised sodium peptone solution into the external jugular vein, after about a minute a small quantity of blood was withdrawn from the carotid artery. This took about twenty minutes to coagulate. Then 50 c.c. of a 1 per cent. solution of calcium chloride was injected, and another sample of blood withdrawn, this clotted in a few seconds. The same result was obtained when leech extract was used instead of peptone. Leech extract probably owes its activity to a protease and is much more effective in hindering coagulation in the case of the rabbit than commercial peptone. The analogy of peptone and soap, which has already been pointed out, also lends support to Pechelharng's views. But I have heard the objection raised that other substances which undoubtedly have a great affinity for calcium do not act in this way and I have been asked whether potassium oxalate acts like peptone. We have put this to the test of experiment and have proved that the injection of a few cubic centimetres of a weak (0.4 per cent.) solution of this salt renders the blood when it is subsequently drawn off very slow in coagulating. In one experiment a sample of blood, which was drawn off before the injection, clotted in less than a minute, after this injection another sample did not clot for seventeen minutes. We thus have an additional confirmation of Pechelharng's hypothesis.

2. The second difficulty may be put in the form of a question. Why do not nucleo-albumens cause coagulation to occur in extra-vascular as readily as they do in intra-vascular plasma? The amount of calcium salts is presumably

the same in both. I have tried a good many experiments with salted plasma, and found, like Pechelharng, that if the nucleo-albumen is previously gently warmed with a little calcium chloride solution it acts like fibrin ferment and causes a rapid formation of fibrin. Calcium chloride alone does not produce this result. But if the treatment with calcium chloride is omitted the nucleo-albumen has little or no activity in this direction; it may even hinder the coagulation on comparison with control specimens of the same salted plasma which has been diluted with water. I feel quite unable to offer an adequate explanation of this difficulty.

3. If fibrin ferment behaves as Pechelharng considers, its action differs from that of all other ferments with which we are familiar. The usual action of a ferment is to act as a water-currer and having given water to the substance on which it acts splitting it into new products takes place (hydrolyses). There is of course no reason why ferments should not act as calcium-carriers but if we include such an action we must either extend the meaning of the term fermentative or abandon the use of the word altogether in speaking of blood coagulation. Of all ferment actions that of rennet in causing milk to curdle is most nearly akin to blood clotting. This resemblance has been a matter of remark from the time of Andrew Buchanan onwards. In each case we have the conversion of a soluble into an insoluble product and in each case the presence of a calcium salt is necessary. Hammarsten showed that the process of milk curdling consists of two distinct stages, and more recently Ringer has confirmed this observation. It appears to me quite probable that in fibrin formation there is a similar double process, the action of the calcium coming in at the end in causing the separation of the clot. But it is very difficult to prove or disprove this idea. As for milk it is possible to boil it without coagulating the proteid, and one can thus destroy the ferment. With blood plasma this is impossible, for the blood proteids are coagulated by heat and so one would destroy both ferment and fermentable substance. I shall however not pretend to be able to decide this question, sufficient data have not yet accumulated for a definite opinion to be pronounced one way or the other and, therefore, I shall for the present retain the use of the conventional term "fibrin ferment."

4. The last difficulty standing in the way of our full acceptance of Pechelharng's theories is that it takes no cognisance of the part that carbonic acid plays in blood coagulation. Clinical evidence supports physiological experiments in that it is the venous blood which is most liable to be coagulated. We can hardly doubt from such evidence that either the quantity or more probably the tension of carbonic acid has an important influence in hindering or promoting coagulation. I must again confess myself unable to see the fallacy of such facts, and I also think that in the present state of our knowledge it would not be safe to attempt any theorising as to the way in which they are to be fitted into Pechelharng's hypotheses.

I may now pass to a more systematic account of the experiments which Mr. Brodie and I have been making during the last two years, they are very numerous, and all I shall attempt is a summary of their chief results. They were commenced with the object of determining whether the nucleo-albumens obtained by the sodium chloride method had the same physiological action as the nucleo-albumens obtained by Woolldridge's acetic acid method and termed by him "tissue fibrinogens." The fact that both produce intra-vascular coagulation formed part of the chain of evidence that the two materials were practically the same upon which I dwelt in my second lecture. The next point taken up was whether the leuthin, which I regard as an important, but to which Woolldridge attached considerable importance, was really the active substance, or whether the nucleo-albumen itself produces the result.

Having shown by experiment that that substance produces its effect merely by its leuthin, whichever of the two methods is adopted for its preparation, the greater number of our subsequent experiments were performed with the material prepared by the sodium chloride method from the thrombus. We adopted this method because it is more rapid and the results obtained were more certain. The material prepared by Woolldridge's method often produces no intra-vascular clotting at all, this was recognised by Woolldridge himself and he spoke of it as the "negative phase" in his experiments, because in the dog which was the animal he chiefly used the blood was not only free from clot but it clotted with readiness after removal from the

1 The term "peptone" includes the proteoses with which I is generally mixed.

We now conclude the portion of the first part of our Commission, which deals with fatalities under chloroform, with a complete tabulation of the cases which have been either reported to us or obtained from published accounts of such deaths. They are necessarily much abbreviated, but contain all the salient features of each case, and as far as possible in the narrator's own words.

an immediate primary result leucolysis or destruction of the white corpuscles, especially of the multi-nucleated ones. The reagents he found which acted in this way were—albumose, peptone, pepsin, nucleic acid, nuclein leech extract, pyrogallin, tuberculin, curare, urea, uric acid and sodium urate. Now Löwit is a strong supporter of Schmidt's views on the preponderating influence of disintegrated leucocytes in bringing about blood coagulation. At the same time he strongly contests Lillenfeld's view that the nuclei participate in the process. He therefore asks why it is that if all these reagents cause leucolysis they do not cause thrombosis, and concludes that what is wanting is the calcium. He accordingly injected calcium chloride either before or after the injection of these other substances and states that he never failed to produce intra-vascular clotting in this way. In our repetition of these experiments we have followed Löwit's directions very closely; we have not been through his entire list, but we have used Witte's peptone, Grübler's peptone, leech extract, curare, urea, uric acid and sodium urate. We have confirmed his results in so far that calcium chloride alone does not produce intra-vascular coagulation, the blood when shed, however, coagulates very rapidly. We found that the same result followed when the calcium chloride was used in conjunction with peptone, leech extract and the other substances just named. With one exception in some twenty experiments we never got a trace of intra-vascular clotting. The one exceptional case was when we used a peptone solution that had undergone putrefaction, and the result might therefore be attributed to the nucleo-albumen in the bacteria themselves. We, however, failed to repeat the experiment in other rabbits with the same solution. That introduces us to another difficulty we have met with—namely the idiosyncrasies of the rabbit tribe. A solution which produces coagulation in one animal may fail to do so in another and it appears that the dark-coloured rabbits are more prone to undergo intra-vascular coagulation than albinos. In connexion with these same experiments I may mention that we found that substances like leech extract which prevent blood coagulation are directly antagonised by solutions of nucleo-albumen, and after the injection of the first the latter still causes intra-vascular coagulation.

Our work, then, has not confirmed that of Löwit, and shows that something else besides leucolysis must occur in order to produce thrombosis. Wright has more recently found that extensive destruction of the leucocytes follows peptone injection. A possible objection to these observations is that the leucocytes may not be actually destroyed, but they run together and get packed away in some organ like the spleen. This view is confirmed by the fact that if one performs the experiment of allowing peptone solution to run into a drop of freshly drawn blood on a microscope slide no destruction of leucocytes is observable. But the phenomena of extra-vascular blood are often so different from what occurs in the vessels that it is not safe to draw inferences from one to the other. We must await further experiments before this matter can be considered settled.

To return now to a question which I have already mentioned—namely the so-called 'negative phase' which sometimes follows the injection of nucleo-albumen. It was first observed by Wooldridge, and more recently confirmed by Wright, that if the blood is not coagulated by the injection it undergoes clotting when shed with great slowness. Wright's hypothesis to explain this is that the nucleo-albumen injected consists of two parts, one the nuclein which produces the clotting and the other is a peptone-like substance which hinders clotting. The negative phase is explained by supposing that the peptone moiety is split off in the circulation and produces there the well known effects of the intra-vascular injection of 'peptone.' This is supported by the observation that in these animals 'peptone' is found in the urine, and further supported by the experiments of Pekelharing who demonstrated the existence of peptone in the blood under similar circumstances.

In a previous paper⁴ I urged that it was not proven that the 'peptone' actually originates from the foreign proteid injected, because the nucleo-albumens fail entirely to give any of the peptone or proteose reactions. I think it much more probable that the peptone originates from the disintegration of leucocytes. Peptonuria ordinarily occurs in suppurative diseases where there is a great deal of disintegration of leucocytes, and I thought one might obtain some light on the subject by the injection of non-proteid materials, such as

curare or urea, which produce leucolysis. In rabbits, however one seldom sees the negative phase, and perhaps our results differ from Wright's because he has chiefly used dogs. We have searched for peptone in blood and urine by Devoto's modification of the ammonium sulphate method, and in some cases by the use of the trichloroacetic acid method. This reagent precipitates all the proteids except proteoses and peptone. Our results are as follows: (1) After the injection of nucleo-albumen, peptone was never found either in the blood or urine, (2) There is no difficulty by either method of recognising "peptone" after intra-vascular injection of small quantities of that substance. (3) After the injection of non-proteid leucocytic agents there is also no "peptone" discoverable by Devoto's method. There were, however, in some cases traces formed by the trichloroacetic acid method after injection of curare and of calcium chloride. I must confess that these experiments do not throw much light on the subject, but as far as they go they tend to support the hypothesis that the "peptone" found by other observers originates rather from the destruction of leucocytes than from the foreign material introduced into the circulation.

Since writing the above, a paper has been sent to me by Lillenfeld,⁵ which bears on this same question. He takes much the same view of the matter as Wright. He calls the substances I have called nucleo-albumens nucleo-histons, on account of the supposed resemblance between the proteid moiety of the substance and "histon," the peptone-like material obtained from nuclei by Kossel. He lays it down as a general rule that substances which hinder intra-vascular coagulation do so either in virtue of the "histon" they contain or the histon they produce by the disintegration of leucocytes, and that substances which produce intra-vascular coagulation do so in virtue of the nuclein they contain or because they cause the liberation of nuclein by the disintegration of leucocytes. If both substances are liberated together the nuclein is the more powerful as a rule and produces coagulation in histon-plasma. From our own experiments I can fully confirm Lillenfeld's views as to the importance of nuclein. I do not regard it as at all necessary, however, to imagine that the nuclein must originate from the nucleus, as the cell protoplasm also contains nuclein in the form of nucleo-albumen. The blood platelets have long been known to have some important bearing on blood coagulation. If the clotting of a microscopic preparation of blood be watched, the fibrin strands are seen to start from groups of the platelets. What blood platelets are has been the subject of much discussion and innumerable theories. I have no wish to add another theory, but will be content with pointing out that the experiments I described on the influence of nucleo-albumens in destroying white corpuscles, and forming from them what look like platelets, favour the theory that these little bodies are the disintegrative products of the leucocytes. Lillenfeld takes the same view, and his micro-chemical method, which shows they are composed of a phosphorus-rich substance, and his further work,⁶ in which by gastric digestion he has separated them into nuclein and albumen adds strong confirmation to this idea. Thus we are brought back once more to the subject of the disintegration of leucocytes, and I will conclude what I have to say on the subject of blood coagulation by a few general remarks on that question.

It was Schmidt who originally taught the importance of the destruction of leucocytes as the main cause of coagulation. These corpuscles are exceedingly prone to undergo changes when exposed to altered conditions, but a considerable change has come over our notions on the subject since that view was first promulgated. Rauschenbach, one of Schmidt's pupils, recognising that numbers of corpuscles do not disintegrate, spoke of a leucocytes which are acted upon and disintegrated by the plasma when the blood is shed, and β leucocytes which remain unaltered. Some very remarkable experiments published within the last few months by Dr Sherrington,⁷ who has succeeded in keeping leucocytes alive outside the body for several weeks in oxalate plasma, have been very strongly against the idea that they are especially prone to disintegrate. The word 'disintegration' does not, however, mean complete destruction and disappearance of the corpuscles in question. It signifies merely retrograde changes that end in the death of the corpuscles. Haycraft regards these changes as being due to mechanical stimulation of living and naked protoplasm by foreign solid matter for if the fluid after being

⁶ Chemisches Centralblatt, 1892, II. 82.
⁷ International Physiological Congress, Liège, 1892.

body I shall later have to return to this question of the "negative phase." Our failures to produce intra vascular coagulation by the nucleo albumen prepared by the sodium chloride method have been very few and are in part to be explained by the fact that the solution had been kept some days before it was used. Most solutions which are active when fresh lose their activity when kept. This difficulty we have now to a large extent obviated by rapidly drying the solution in a vacuum over sulphuric acid. The powdered substance, which contains both the proteid and the sodium carbonate used to dissolve it, is readily soluble in water. The solution is viscid, but after filtration it is perfectly clear and free from solid particles. In all our experiments we have paid attention to this point, all our solutions have been thoroughly freed from solid particles by filtration. I may perhaps now describe an experiment with its ordinary results. The animal, and we have used rabbits almost exclusively, is anaesthetised with ether and fixed in a holder in the usual way. The external jugular vein is exposed and a cannula inserted, through this the solution is injected and about 10 cc. of the solution (which would contain approximately 0.05 grammes of proteid) is usually sufficient to cause death. The animal dies within a few seconds, the respiration suddenly stops, there is no dyspnoea as a rule, but there may be a slight stretching movement. Another marked symptom is extreme exophthalmos and dilatation of the pupils. The post-mortem examination is performed as rapidly as possible and the thrombosis found is usually limited to the venous blood, but in many cases there is extensive clotting in the arteries also. We have not often found a clot in the portal vein. The heart is still beating, the right side full of dark clot, the left usually empty, or it may also contain clot, which however differs from that on the right side in being bright red. Death is thus evidently due to failure of respiration, and the question arises whether the respiratory centre is at fault or whether the primary cause is to be sought in the lungs. The sudden stoppage of respiration and the absence of dyspnoea point to the respiratory centre, and this is confirmed by the fact that the severance of both vagi makes no difference in the experimental result.

I must next pass to an entirely different series of experiments. I believe that our experimental methods are so far in advance of those of many other investigators in that the solutions we employed were perfectly clear, but we sought to purify the substance we employed still further. This was done by taking the nucleo albumen, grinding it up once more with sodium chloride and reprecipitating it by throwing it into excess of distilled water. This was repeated two or three times. The material obtained by twice repeating the process is absolutely free from lecithin and produces on injection the usual thrombosis, but if the material is still further purified it fails to produce any result whatever on injection, though the solution is still viscid, 200 cc. or more may be injected, and on killing the animal by asphyxia not a trace of coagulation is found anywhere. We have verified this very disappointing experiment half a dozen times and then sought for an explanation. Evidently in the process of purification some substance is removed from or added to the nucleo albumen, which in consequence loses its activity. We noticed that during the processes of repeated washing there was a considerable loss of material, the nucleo albumen collects as a scum on the surface, but if it is allowed to stand some passes into a condition of semi solution in the weak saline underneath it. Injections of this, however, led to the same negative result. On the supposition that purification had removed something from the nucleo albumen, we proceeded to investigate what that something was.

Our previous experiments had shown us that lecithin is not the active substance, and moreover the substance which after one or two washings causes thrombosis and that which after three or four fails to do so are both equally free from lecithin. The hot alcoholic or chloroformic extract of both contains absolutely no phosphorus. Is it then calcium? Again the answer is, No. Injection of the purified material plus calcium chloride is quite ineffectual in producing thrombosis, and analysis of the ash, both of the purified and the unpurified substance, is either entirely free from calcium or contains only imponderable traces. The only other alternative which suggested itself to us was whether purification had removed the nucleic acid. The proteids are substances which are prone to undergo intramolecular rearrangements, and it is quite possible that this occurs on frequent precipitation and solution. The idea that the nucleic acid is split off from the proteid proper

during these processes was by no means improbable, especially as Dr Starling called our attention to the fact that Wooldridge found that his "tissue fibrinogens" lost their activity after purification. Now, repeated treatment with acetic acid (which is Wooldridge's method) would perhaps result in displacing a weak acid like nucleic acid, and there is no *a priori* reason why repeated treatment with water and sodium chloride should not do the same. Accordingly we put the hypothesis to the test of experiment. We have not yet had time to perform many analyses, but so far the result has been again negative. The so-called pure material contains the same percentage of phosphorus as the active substance. If, therefore, we wish to avoid the unsatisfactory conclusion that what we have removed is an intangible and shadowy substance known as a ferment, it is necessary to fall back on the other hypothesis and consider whether in the process of purification we have added something to the nucleo albumen. A few days ago at the Physiological Society Dr Haycraft suggested that by the repeated use of salt we have obtained an inactive sodium chloride compound of the proteid. This will have to stand or fall by the test of analysis, but it appears to me to be a very probable explanation.

All observers are agreed, with the exception of Dr. Wooldridge, that these corpuscles play an important part in the coagulation process, and we can hardly doubt that the fibrin ferment or nucleo albumen which causes blood to clot when it is dried originates from the leucocytes. And here I would emphasise the importance of comparisons between vertebrate blood and the blood of the crustacea. Hardy¹ has recently shown that here certain corpuscles which he very appropriately designates the "explosive" corpuscles yield the fibrin ferment, and Griesbach² has accentuated this point by showing that agents which, like osmic acid, prevent the explosion of the corpuscles, lead to a loss of coagulability. Now it struck us on reading Pechelbarr's papers and on performing our own experiments that they did not definitely prove that the ferment is actually formed from the foreign proteid introduced into the circulation. It appeared quite possible that the ferment may, at any rate in part, originate from the disintegration of blood corpuscles within the blood stream. Buchner has devoted a great deal of study to the protective proteids or alexines. Like Doremberg, he finds that these substances are not merely bactericidal but also globulicidal, that is they produce not only disintegration of bacteria but of blood corpuscles also. Now that we know that the alexines are nucleo albumens, it appeared probable that their globulicidal properties would partly explain intravascular clotting. On the other hand, we know that substance-like distilled water, which produces extensive disintegration of the corpuscles, never cause thrombosis. Now, our solutions of nucleo albumen do produce extensive disintegration of corpuscles. Testing the matter on a slide with a drop of human blood, we saw that the red corpuscles were made irregular in shape and to a slight extent dissolved. The white corpuscles are broken up immediately and form first a mass of adherent particles, which then separate and look just like "Blutplättchen." But exactly the same result is obtained with solutions of the purified material which produce no thrombosis, and very nearly as extensive disintegration is produced by the sodium carbonate solution which we use as the solvent of the proteid. Counting experiments performed on rabbits led us to the same conclusion. Injection of the nucleo albumen produced a slight lackness of red corpuscles. This is evidenced also by the slight cakiness of the blood often seen. The loss of white corpuscles is much more marked, being from 90 to 100 per cent. The loss from injection of a corresponding volume (20 to 50 cc.) of sodium carbonate (5 per cent solution) alone is nearly as great—75 per cent. The loss always chiefly falls on the multi nucleated corpuscles. We have thus something more to reckon with than mere destruction of leucocytes, and we can hardly resist the conclusion that it is the foreign material introduced into the circulation that furnishes the active substance that produces thrombosis.

We should not have pursued the matter further if a remarkable series of papers by Löwit³ had not at this stage of our work fallen into our hands. He also has used rabbits in his experiments, and he finds that many reagents which, when intravenously injected, cause leucocytosis produce as

³ Studien zur Physiologie und Pathologie des Blutes und des Lymphs. By M. Löwit. Jena G. Fischer 1892.

of an agreeable disposition and an indomitable spirit of independence.

Present condition.—Her general configuration is stout and clumsy, her expression when speaking is intelligent and cheerful, otherwise (see Fig 2) heavy and dull. One is struck by the large size of her head and face, and also of her hands. Height, 5 ft 4 in., weight, 111 st.

Head and face.—The head is much larger than normal (see measurements below), the occipital protuberance is pronounced, the lambdoidal suture is well marked, but the other sutures and protuberances are not specially prominent, with the exception of the supra-orbital ridges which give a receding aspect to the brow. The hair is abundant dark brown and of normal quality, the ears are normal in size, the tissue perhaps is thickened, the complexion is pale, there are shallow horizontal wrinkles on the forehead. The eyelids are heavy, the nose is straight and large, with a slight upward curve near the tip, the alae are thick, the lips are thick, the lower one being heavy and hanging, the mucous membrane of the lips is normal, the lower jaw is large and the chin double, the angles of the inferior maxilla are more obtuse than normal, the lower teeth are in normal relation to the upper, the teeth are very bad and have been so since she was sixteen years of age—there are small gaps between them. There is a small metal plate in the upper jaw

FIG 2.

with four incisors and the left canine. This was put in eight years ago and suited, now it is loose and there is room for another tooth beside the right canine. The hard palate is flat and extensive, the soft palate and pharynx are flat and extensive in proportion. The tongue is broad (6 cm.) but not markedly thicker than it should be. It is slightly cracked and fissured and indented by the teeth at the edges, the patient feels as if it were uncomfortably big especially when speaking. She has had this feeling since she had an inflamed sore-throat three years ago. The voice is rather husky, she was a fairly good singer, but now the voice has deteriorated in quality and also in range of pitch (being lower by two notes), the pomum Adam is not prominent, the thyroid gland is larger than usual, both lobes being easily felt.

Trunk.—The antero-posterior curvature in the dorso-cervical region with its concavity to the front is very marked, also in the upper dorsal region there is slight right lateral curvature. The patient is very quickly tired if she tries to hold her head erect. The ribs are broad, the costal cartilages and sternum are normal, the circumference at the nipples is thirty-five inches and a half on expiration and thirty-seven inches on moderate inspiration, the pelvic bones seem normal, the breasts are poorly developed and have always been so. The cardiac dulness is normal, there is a small area of dulness the size

of a crown piece, behind the manubrium and the first left costal cartilage.

Upper extremities.—The clavicles are thick and long, the scapulae and humeri seem normal, the arms are well-formed down to the wrists, the wrists, and especially the hands are greatly enlarged, the hands are very inelegant (see Fig 3), being thick and broad, fulness is specially developed in the hypothenar eminences, the markings on the skin are normal, the veins on the back are easily seen, the thickening seems to involve the bones as well as the subcutaneous tissue, the lower ends of the radius and ulna participating, the fingers have a stumpy appearance, not tapering or only very slightly, as shown by measurement, the nails of the fingers are flattened out, slightly curved for-

FIG 3

wards in the terminal third and much broader in proportion to length than is normal, the thumbnail is an ellipse with the long axis transverse, the nails used to crack unpleasantly. The outer layer peeling off, there is no abnormality in consistency during the past two years.

Lower extremities.—The right knee is occasionally painful, especially after kneeling, a little crackling is felt in the joint on flexion, recently there was an attack of housemaid's knee on the left side, the bones and other tissues down to the ankles are increased in bulk, the feet are comparable to the hands in size and clumsiness (Fig 4), there are no callosities.

FIG 4

and there is a general thickening and enlargement. The big toes gave much trouble till operated on in 1890, through ingrowth of the nails. This of course, was owing to the difficulty in getting large boots. The toes have a compressed appearance and would be square on section, the nails are like little ellipses with the long axis transverse and are embedded in the skin, there is a tendency to flat-footedness.

Muscular system.—This is to all appearance well developed, the grip of the hands is very much less than normal, the muscles at the elbow and knee seem about normal. Lifting heavy weights gives a sensation of strain in the upper extremities.

shed is surrounded by a fluid like oil coagulation is prevented. By watching the corpuscles under the microscope he has shown that they become flattened and irregular, they then lose their granules, or these retire to one part of the cell, leaving the rest clear. Such changes are better marked in the coarsely granular corpuscles than in the finely granular ones. He regards the shedding out of the fibrin ferment which accompanies these changes rather as a process of metabolism than of disintegration. I am inclined to adhere, however, to the old word disintegration, as what goes on is something different from what occurs in normal metabolic processes. As I pointed out some years ago, the disappearance of the granules from the cells inevitably suggests a comparison between the process and secretion, in which the shedding out of a ferment by secreting cells is accompanied by the disappearance of the granules which indicate the existence of its zymogen, or mother substance. This idea has since been verified by the discovery of the zymogen of fibrin ferment, and so strongly has the resemblance to secreting cells been recognised that some have gone so far as to speak of the coarsely granular or eosinophile cells as unicellular glands having a different origin and function from the neutrophile or finely granular cells which appear to be the principal phagocytes. Hankin⁸ has arrived at the conclusion that the alexines or protective proteids which confer bacteria killing power on blood serum originate from the eosinophile cells, and this bears upon our present question because of the similarity, or it may be identity, between fibrin ferment and the alexines. There is, however, evidence that cells which are not eosinophile may yield fibrin ferment. The explosive cells in crustacean blood are hyaline, not eosinophile. (Hardy.) According to Sherrington, too, the eosinophile cells are not fibrino-plastic. I think it would be premature to lay down any definite rule as to which group of corpuscles fibrin ferment comes from, and further, seeing that substances which produce coagulation can be obtained from cells as diverse as those in the thymus, brain, liver, testis and kidney, it seems very probable that both kinds of leucocytes in the blood may give rise to fibrin ferment, they both consist of protoplasm, and the main proteid constituent of all protoplasm is nuclealbumen.

During these lectures I have from time to time stepped aside from my subject proper in order to point out certain practical bearings which I considered to be of importance. I wish that I had had time, and still more the necessary experience, to have done so more fully. If however, any grains of usefulness are scattered through what I have said, there is no doubt that others will pick them up and work out their practical side. In connexion with blood coagulation and thrombosis I need not stop to point out the immense importance of a correct knowledge of this subject to the pathologist, and I will content myself with two remarks only on its practical aspects. The first of these is to point out the great resemblance between the phenomena observed in the animals in the experiments described and those cases of pulmonary thrombosis which are occasionally seen in the human subject. One can hardly doubt that here we have to deal with poisoning by the same material. Professor Gerald Leo was witnessing some of our experiments a few days since, and he described to me a case he had had in King's College Hospital.⁹ It was one of "rupture of the breast for cancer, and the wound was perfectly aseptic, but ten days after the operation, without any warning the patient died suddenly with great dyspnoea. Examination of the brain revealed no lesion, but at the necropsy a firm fibrous clot was drawn like a tree with its branches from the pulmonary artery. The dyspnoea in this and similar cases points to the cause of death in the lungs themselves rather than in the respiratory centre, this difference is easily explicable on the ground that the dose of poison enters the circulation more slowly than in our experiments where it is injected. The second practical point which I wish to emphasise is a word of warning. When I have seen animals die in a few seconds, as though by a lightning flash, after a dose of five cubic centimetres of this poison, which could not have contained more than a few centigrammes of the material, I feel very loth to urge that any practical use of such substances should be made in the human subject either for the stoppage of hæmorrhage or for the production of a clot in aneurysms. The cure would in such instances be worse than the disease.

A CASE OF ACROMEGALY

By J MACKIE WHITE, M.A., M.B. EDIN., M.R.C.S. ENG.,
PATHOLOGIST TO THE DUNDEE ROYAL INFIRMARY.

THE subject of the following notes first came under the observation of Dr Alexander Campbell and myself in September, 1890, on account of ingrowth of nails on both her great toes. My description was taken down at that time, but, as it has recently been verified and slightly added to, I shall speak of her as she is now, merely premising that no alteration of any importance has occurred during the past two years. She is a domestic servant, single, aged twenty seven, and enjoyed good health, being strong and fit for her work till 1886. Her family history throws no light on the case. The mother is alive and healthy, of slight build, and below the medium size. The father died of paralysis five years ago, aged seventy. The maternal grandfather lived to be eighty years of age, the maternal grandmother died of "dropsy," aged fifty. The paternal grandparents died in old age. A sister and two brothers are alive and healthy, the youngest brother died of typhoid fever twelve years ago. From her personal history syphilis and alcoholism can be absolutely excluded, and her surroundings have always been favourable to health. Fig 1, engraved from a photograph taken in 1884

FIG 1

Engraved from a photograph taken in 1884 before onset of illness.*

shows her to have been then rather slim in build, with a bright expression, thin lips and other features and small well shaped hands. About the time of onset of her present illness, namely in 1886 she was subject to certain depressing emotions. In that year she observed that she became more easily fatigued, and in the course of a few months great physical changes occurred. Menstruation, which had begun at fourteen and been normal hitherto became scanty and in six months finally ceased. Her body became stouter, so that with her ordinary clothing breathing was greatly impeded. To get up from the kneeling posture she had sometimes to roll over on her side. Her face changed to such an extent that friends who had not seen her for some time failed to recognise her. The size of her gloves increased steadily from No 6½ to No 8 and her shoemaker was troubled with the difficulty of procuring "tops" remarking with somewhat ungallant candour that he had never known a woman to have so large a foot. The actual increase in the size is given as from No 4 to No 7. Profuse perspirations, violent headaches occipital and frontal and a feeling of stiffness as if she was encased in starch were amongst her troubles. The various changes seem to have been coincident, although the muscular weakness first attracted her own attention. In spite of her physical disability she managed to keep her "places" being possessed

* Centralblatt für Bacteriologie und Parasitenkunde, Bd. xii., Nos 22 and 23.

⁹ Many similar cases will be found in Sir J. Fayer's Clinical and Pathological Observations in India.

There is, however, one district which forms an important exception to this general statement, and proves that elevation is not the sole factor that determines the severity of a cholera epidemic. In the hilly province of Daghestan, which borders the Caspian Sea, the proportion of population attacked by the disease was higher than in any other district of the Caucasus. Further, in this province and in that of the Terek, lying adjacent on the north, cholera raged with greater violence than in any other part of Russia, European or Asiatic. From a comparison of the figures in the table with the position of the provinces on the map it will be clearly seen that the cholera epidemic was very much more intense in the eastern districts of the Caucasus than in the western. In the southern division of the country this difference was very marked. In the province of Daghestan and the government of Baku, lying on the east, the proportion of cases per 100,000 inhabitants was, in the first, 3911, in the second, 1593. In the government of Kutais, lying on the Black Sea littoral, the proportion was represented by the insignificant number of 6, whilst the intervening governments were affected in ratios varying from 726 in Tiflis to 1344 in Kars. The same gradation appears in the northern Caucasus. The numbers in the three districts, into which this part of the country is divided, were as follows. In the easterly province of the Terek and of Stavropol in every 100,000 inhabitants there were respectively 3383 and 2115 cases of cholera, whilst in the westerly province of the Kuban there were only 1911. This difference may have been partly due to the intensity of the epidemic becoming weaker as it travelled further, but it is not uninteresting to note that there is a considerable difference in level between the eastern and western coasts of the Caucasus, the whole country trending downwards from the Black Sea to the Caspian Sea. The average level of the Caspian Sea has been estimated to be 85.45 feet below the level of the Black Sea.² It would be asserting too much to say that in this difference in level is to be found the sole explanation of the difference in intensity of the cholera epidemic, but it is at least an interesting and suggestive coincidence if nothing more.

The climate of the Caucasus is most varied. Owing to the mountainous nature of a great part of the country almost every degree of temperature may be experienced by the traveller in simply passing from shore to shore. The heat in summer, particularly in the northern steppes, is often very great, and the cold in winter is frequently extreme. In many parts a difference of as much as 60° or 70° F. is observed between the average temperatures of the hottest and coldest months, whilst the range between the absolute maximum and minimum may be nearly twice as great. The inhabitants of the Caucasus are as varied as the climate. The country has been proverbial from the time of Pliny for its confusion of tongues. Great as is the number of races, it appears to be greater from the fact that every tribe is known by a different name to each of its numerous neighbouring tribes the names being thus multiplied many fold. A further confusion arises from the existence of many dialects in a single language, the Armenian alone being said to possess no less than twelve. The majority of the inhabitants of the mountainous regions is made up of Armenians, Georgians, Ossetians, Kurds, Turks, Turcomans, Tocherkesses, Tchetchentsy, and Kalmuck and Nogai Tartars, in addition to the Russian population that has settled there since the country came under the rule of the Czar. In the steppes the population consists almost entirely of Cossacks of the Terek and the Kuban. The larger number of these races lead a half settled, half nomadic life, occupied partly in agriculture, partly in pasturage, and partly, though now to an insignificant extent, in brigandage and robbery. Their social customs and their religious prejudices have probably each played their part in assisting the wide spread of the recent epidemic. I take their social customs first. Throughout the Caucasus there is no system of drainage, the "Persian" or "dead well" being the sole method in use for disposing of sewage matter. These, as described before, are very deep wells or holes in the ground, which are gradually filled with human excrement. The harmful effect of this system has been pointed out in the Annual Report of the Medical Department. The accumulation of such enormous masses of human excreta in the earth and the consequent pollution of the soil have gone so far, the report states, that a foul odour is observable in the basements of many houses and

in some ice cellars in towns where this system is in use. In the flat plains of the Northern Caucasus it is easy to understand how the wells or springs, which are the sole source of the water supply, may become contaminated by this method of disposal, or, rather, preservation of sewage.

The houses of most of the hill population are flat roofed *sallhi* or huts, badly built of wood, stone or clay, and in many cases very much more than half underground. On the high table lands throughout nearly the whole of Transcaucasia the Georgians, Tartars and Armenians live in the so-called *zemlianki* or underground "earth huts." Dwelling at a height of some thousand feet above the sea, where the thermometer in winter may fall to 30° or 40° below the Fahrenheit zero, such houses provide the greatest amount of warmth at the smallest cost. A short description of one of these dwellings, taken from the Journal of the Imperial Caucasian Medical Society, may be of interest. Each house always contains more than one room and may sometimes form a labyrinth of rooms connected by passages. The floor is generally about one sajene (seven feet) below the surface of the earth. The roof is about two feet above the surface and is covered with brushwood and then with a thick layer of earth. A few small openings exist in the roof for the admission of light and air, but in winter these are almost invariably closed at night to keep in the warmth. There is generally one door leading to the men's rooms and a second to those occupied by the women, who, as in all Mohammedan countries, live apart. In the centre of the establishment there is generally one large room devoted to the cattle, which share the same roof as their masters for at least six months in the year. In the living rooms there is generally a hearth in which dried cow dung is used as fuel. In such a house the Caucasian Highlander spends at least half the year, in an atmosphere that, to anyone not used to it, is quite intolerable. Heated by the fires and by the warmth of the cattle, almost unchanged by ventilation, polluted by the breath and by the exhalations from the bodies and from the excreta of many human beings and of a number of cattle, varying from units up to hundreds, the air becomes fouled to such an extent that it seems incredible that life can be supported. Dr. Uspenski, a Russian who was forced by stress of weather to seek the hospitality of the owner of one of these dwellings, relates that the atmosphere was so unbearable that, notwithstanding that a fearful snow-storm was raging outside, he was obliged to rise, mount his horse and face the weather as being the lesser evil of the two. The cattle suffer terribly from the confinement and when let out in the spring are little more than living skeletons, as the result of the darkness, want of exercise, scanty food and foul air. The soil must be no less foul than the air, the "dead well" receives the human excreta and the surface of the earth must be considerably polluted by the excreta of the animals, although these are carefully collected every day in order to serve as fuel. When it is added that the well which affords the sole water supply is usually under the same roof, it is obvious that to polluted air and polluted soil must be added polluted water. That people living in such surroundings were severely visited by the cholera epidemic is not surprising. If unhygienic domestic conditions seemed to invite the introduction of the cholera infection, religious prejudices were doubtless powerful aids in propagating it. The predominant religion in the Southern Caucasus is Mohammedanism, professed by 48 per cent of the inhabitants, members of the orthodox Greek Church form 29 per cent, Armenians 20 per cent., and the remainder is made up of Russian sectarians, Roman Catholics, Jews and followers of other faiths in insignificant numbers.

The fatalism of Mohammedans is proverbial and must have had much to do with the spread of cholera in a country where nearly half the population are followers of the Prophet, whilst their religious objections to seeking medical aid, their peculiar rites in disposal of the dead, and their occasional inflictions of self torture must have been powerful factors in disseminating the epidemic. Scarcely less fatalistic than the Mohammedan is the Russian sectarian. Of the Cossack population of the Northern Caucasus more than half belong to one or other of the numerous sects of the *Raskol* or Dissent. Many of them are descendants of dissenters exiled to the Caucasus by the Emperor Nicholas for refusing to disclaim their heretical opinions and subscribe to the Orthodox Church. Whilst some, as the Molokany and Dukhobortsy, are rationalistic in their tenets and live a quiet industrial life, others, as the Khlysty, are highly fanatical, their so-called services being in many cases merely disgusting exhibitions of sensuality. The prevailing disease in the Caucasus is malarial fever, but the cause of the greatest

¹ The Russian administrative terms "oblast" and "gubernia" are here rendered province and government respectively.
² This fact was established by the scientific expedition sent by the St. Petersburg Academy in the years 1836-37.

region and up the back of the neck, the general activity is greatly impaired, the gait is clumsy.

Nervous system.—The special senses are normal, with the exception of sight. Dr McGilivray kindly examined her eyes for me, and he gives the following exhaustive report: "Nov 14th, 1890.—The patient feels pain in the eyes, with frequent attacks of frontal headache, she complains of dimness of vision and great difficulty in reading, as the letters jumble up, she first noticed that her sight began to fail about a year after the onset of her present illness, up to that period her eyes had been perfectly well. There is slight hyperemia of the palpebral conjunctiva and thickening of the eyelids in both eyes, there is no exophthalmos, the pupils are normal in size and react well to light and accommodation, the movements of the eyeballs are normal except for a jerky rotatory nystagmus when the patient tries to look to the right and left, but less marked in the former direction, pressure backwards on the eyeballs conveys no cushion feeling to the fingers and causes no pain to the patient, tension is

normal. Vision Right and left eye = $\frac{6}{9}$ c. + 1 D cyl = $\frac{6}{5}$

She reads Jaeger 1 at eighteen centimetres with the right eye, and Jaeger 1 at twenty one centimetres with the left for a few seconds only. The range of accommodation is very limited. With the above correction the range of accommodation is improved. At twenty five centimetres there is marked insufficiency of convergence, there is no diplopia, the fields of vision are normal, as also are colour and light sense. Ophthalmoscopic examination shows no abnormality. Feb 10th, 1892.—The patient was re examined. There is no alteration in the above symptoms except that the patient thinks the vision is improving and the headaches are less frequent and not so severe. Spectacles were not prescribed."

General sensibility.—The patient experiences a sensation of numbness in the fingers in the morning, lasting from ten to thirty minutes. The fingers feel dead, but do not change colour. The sensation of touch is then greatly impaired or lost. On the outer side of the right thigh from above the knee to near the hip she experiences occasionally a tingling sensation, especially if tired after standing. Slight pressure causes a painful feeling at those times, but firm rubbing gives relief. The sensation is not that of "sleeping." She cannot bear tight bands about the body. She has, as noted in the history, been a martyr to headaches, but these have been much less severe during the past year and generally yield to antipyrin. She can go to sleep at any time, day or night. Since the onset of her illness she has been very nervous, being easily startled and being then affected with palpitation and a breaking out of perspiration. There is no mental deterioration.

Skin &c.—The skin is rather coarse. In the region of the neck there is a large number of small warts, varying in size from that of a pinhead to that of a millet seed (they seem to be simply cutaneous); perspiration is constant, especially in the palms of the hands and the soles of the feet (it has become rather worse during the past year), the appetite is normal, but temporarily affected by headaches, thirst is great, but the urine is normal in quantity and is free from sugar and albumen, the pulse is 60, regular, and of fair strength, the heart, lungs and other organs are normal.

Measurements in centimetres.—Circumference of head, 57.5 cm, occipito frontal diameter, 18.5 cm, bi parietal, 15 cm, bi mastoid, 11.5 cm. Length of ear, 6 cm. From the roots of the hair to the tip of the nose, 13 cm, of which the nose measured 6 cm. Breadth of nose at alae, 5 cm. Inferior maxilla from angle to angle, 21.5 cm., length of ascending ramus, 3.2 cm. Circumference of neck at the thyroid isthmus, 36.5 cm, length of the sternum 21 cm. Distance between anterior superior spines, 28 cm. The clavicle of the right arm, 15.5 cm, tip of acromion to point of the mid finger, 67 cm, circumference of arm at top 31 cm, at middle, 29 cm., above elbow, 26 cm., at elbow, 28 cm, circumference at mid forearm, 23 cm, at wrist, 18 cm, length of hand from lower wrist crease to tip of mid finger, 18.5 cm, circumference at metacarpo phalangeal joints, 23 cm., thumb length, 6.4 cm., circumference, 8 cm, index circumference at root 7.8 cm, at first joint, 7.8 cm, at second joint, 6.8 cm. Right lower limb. Length of femur, 45 cm, vertical diameter of patella, 6.5 cm, transverse diameter, 7.3 cm, circumference of knee, 37 cm, of calf, 37 cm, length of tibia, 35 cm, circumference round malleoli, 26 cm, over heel and front of ankle, 32.5 cm, at first metacarpo phalangeal joint, 23.5 cm, length of foot, 25.5 cm, circumference of great toe at root 9 cm, at nail, 9.5 cm.

Remarks.—The case is clearly one of acromegaly, typical

in its onset and its present aspect. The diagnosis could be made with positive certainty from the history alone, the alterations in fit of gloves, boots and tooth plate being conclusive. This patient is not so extreme a case as are many that have been described, the absence of prognathism to any great extent being of importance in allowing a natural expression to remain. The comparatively short duration of the malady and the present arrest of its progress are worthy of attention in this respect. It is easy to see how this disease remained unrecognised till Pierre Marie pointed out the features which distinguish it. Such a patient as the above goes on long enough satisfied with her friend's diagnosis that she is getting stout &c., simply taking medical advice on one or two common symptoms. Further, there is a misleading symmetry about the enlargements in most cases. The tongue, for example, is absolutely large and is indented by the teeth, but it lies fairly easily in the very capacious mouth. The facial part of the head is in proportion to the cranial, and the neck and trunk are correspondingly stout. The hands and feet again, whilst large, both absolutely and relatively, in comparison to the rest of the limbs, are, as Marie said in his original paper, in themselves regularly formed. Still, an attentive examination of their shape, especially the want of proportion between breadth and length and the "sausage" look of the fingers, makes one see that they would be unnatural even to a glintless. As the total number of cases of acromegaly as yet described is under fifty, I hope that the above record will have a certain value.

Airlie place, Dundee

THE CHOLERA EPIDEMIC IN RUSSIA

BY FRANK CLEMON, M D EDIN &c

NO II.—IN THE CAUCASUS

GEOGRAPHICALLY the great mountain chain of the Caucasus is generally considered to be the dividing line between Asia and Europe, but administratively the whole of the Caucasus, including a considerable portion of the steppe lying to the north of the mountain chain, is included in Asiatic Russia. In the last article the cholera epidemic was traced throughout the Central Asian provinces and Siberia from its first introduction to Russian soil at Knochka. In the present it is proposed to deal with it in the Caucasus in a similar manner. The Caucasus occupying the stretch of country between the Black and the Caspian Seas has a superficial area but little smaller than that of France or Spain. It is continuous on the north with the country of the Don Cossacks, from which it is separated by two small rivers, whilst on the south another river—the Araks—forms the natural boundary between this part of Russia and Persia. The country is farther clearly divided into two parts, not only by an administrative division, but by marked geographical differences, which played an important part in affecting the relative intensity of the cholera epidemic in the two districts during the past summer. The Northern Caucasus is, for the most part, a flat but fertile steppe, watered by few and sluggish streams, and in part by artificial irrigation canals, but at its southern edge, as it approaches the mountainous region of the Southern Caucasus, the character of the country changes. It becomes sub-mountainous, with rapid streams flowing into the channels of the rivers Terek and Kuban. The Terek flows into the Caspian Sea, the Kuban into the Black Sea, neither receives any tributary from its northern bank, both being fed entirely by the mountain streams from the south. The Southern Caucasus, or Transcaucasia, is in many respects in marked contrast with the northern division of the country. Briefly, it consists of a series of immense mountain chains culminating in the peaks of Elbruz and Kazbek, and watered by innumerable rushing streams which mostly unite to form the channels of the River Kura, flowing eastward into the Caspian Sea and of the River Rion, which empties itself into the Black Sea. That elevation has an important influence in modifying the intensity of a cholera epidemic has been very generally admitted, and is to a great extent supported by the behaviour of the present epidemic in the two divisions of the Caucasus. In general terms the flat low lying plains of the Northern Caucasus were very much more severely visited than the high and mountainous regions of Transcaucasia. This is clearly seen from the figures given below. In the three northern provinces out of every 100 000 inhabitants 2390 were attacked by the disease, whilst in the southern only 1831 suffered.

MAP OF THE CAUCASUS.

number of deaths is gastro-intestinal catarrh, connected, it is supposed, with the frequently polluted water supply and with the custom of the inhabitants of eating large quantities of unripe fruit and vegetables. The prevalence and fatality of gastro-intestinal catarrh are by no means confined to this part of Russia. It is responsible for a larger total of deaths than any other single disease or group of diseases in almost every town throughout the empire. In the six towns—St. Petersburg, Moscow, Vilna, Saratof, Odessa and Baku—which may be taken as fairly representing all parts of European Russia and the Caucasus, in the three years 1887-89 there were 41,649 deaths from this one disease, from the next most fatal group of diseases, those of the respiratory organs, there were 31,821 deaths, and from tuberculosis, 27,916. This widespread existence, particularly during the summer, of gastro intestinal catarrh is a fact of the first importance in the epidemiology of cholera in Russia, and probably in it is to be found the reason why the cholera infection, once fairly introduced into the country, has generally spread unchecked throughout the whole of the empire. So long as the cause of it exists, and particularly so long as the water supply of the towns and villages remains what it is and the local authorities continue indifferent as to its source and purity, the Russian people must form a happy hunting ground for the cholera bacillus, and in all probability all efforts to check its spread when once it has passed the frontier will be futile.

The cholera was imported to the Caucasus at its most vulnerable point. The town of Baku lies on the coast of the Apsheron peninsula, which juts into the Caspian Sea almost exactly opposite the terminus of the Transcaspiian Railway at Oozoon Ada on the east coast of that sea. Between the two ports there is frequent communication, they lie 132 miles apart and the crossing takes about twenty seven hours. The first cases of cholera occurred in Baku on June 6th,³ eighteen days later than the appearance of the disease on Russian soil at Kaachka and twelve days later than the first cases in Oozoon Ada.

Baku is a large town that has increased immensely in the last few years. In 1888 the population was less than 46 000, a year later it had nearly doubled itself, and this year the town is reckoned to contain 108 000 inhabitants. This rapid growth is closely connected with the extraordinary development in the trade in naphtha, which is found in large quantities in the neighbourhood. The air reeks with its fumes, and the water of the harbour is covered with a film of it. If one may believe a recent correspondent of a Russian newspaper the naphtha fumes have a disastrous effect on all vegetation. The town, it is said, "contains gardens without grass, trees without leaves, sea without water, and steppes without air, for it is as impossible to call air that kerosene vapour which blows round Baku for many versts as it is to call water that mother of pearl tinted, heavy mud which creeps into the harbour, taking every colour of the rainbow in the sun." The water supply of Baku appears to be a matter of difficulty. It is obtained from wells, but, lying as the town does on a bare and sandy peninsula surrounded by the sea, the well water is hard, rich in salts and deposits a sediment. The inhabitants of the hills at the back of the town have a much better water supply from springs and streams. The town has, besides its Russian part, an Asiatic quarter surrounded by old fortifications and inhabited by the poorest of the labouring classes, a population consisting of Tartars and Persians living in a state of indescribable Oriental filth and innocent, it need scarcely be added, of the most rudimentary measures of hygiene or sanitation. It is not surprising that the cholera, when once introduced into Baku, spread rapidly and almost at once assumed serious proportions especially as few measures of precaution were taken by the local authorities until the disease was well established in the town. Then panic rendered firm or united action on the part of those in power impossible. The hospital accommodation was found to be inadequate, the number of medical men insufficient, and a total absence of disinfectants rendered still more hopeless any efforts on the part of the sanitary officials. All who could fled from the town, the trains were besieged, the stations packed with crowds unable to find room in the trains, shops and factories were closed and business came to a complete standstill. One of the few measures taken by the authorities was that of watering the streets with *mazut* the refuse from the naphtha refineries, presumably under the impression that it possessed disinfecting properties. Its utter failure in Baku to check the epidemic

is a practical confirmation of the experiments of Koch, who found that neither pure petroleum ether nor benzol had any effect on spores exposed to their action for five and for twenty days respectively. During the seventy eight days that the epidemic lasted in Baku there were 1834 deaths from the disease.

From Baku the infection spread as from a centre. A consecutive itinerary of its course is impossible, as it was not following one line but was appearing at the same time in many towns widely apart. In Tiflis, in Elizavetpol, in Zakataly, in Petrovsk and in many other places the earliest cases were amongst refugees from Baku and preceded by some days cases amongst the residents of those towns. The Transcaspiian Railway, which connects Baku with Batoum and Poti on the Black Sea, was one important channel of infection, but the disease appears to have spread as much if not as rapidly, by road and sea as by rail. Tiflis, one of the earliest towns affected, lies on the railway about eighteen hours' journey from Baku. With a population of 102,000, it possesses the great advantage of a good water supply derived from springs in the hills ten versts away and brought to the town by an aqueduct. The water is stated to be remarkably pure, and it is doubtless owing to this fact, together with the high position occupied by the town, that Tiflis suffered so comparatively lightly from the epidemic. The first cases occurred on June 13th and the total number of cases reported was 570 and of deaths 261. On June 14th cases occurred in Petrovsk on board a steamer coming from Baku, on the 16th the disease was reported from Shusha and on the 18th from Elizavetpol. Before the end of June it had reached the Northern Caucasus and cases occurred in the Terek province and the government of Stavropol. Early in July the disease appeared in Erivan and in Kars, and before the middle of the month every district of the Caucasus was suffering more or less severely. In the three northern provinces the epidemic was raging violently, between two and three thousand cases and half as many deaths being reported daily. In the province of the Terek, in particular, the numbers were very high. The capital of this province is Vladikavkaz, important as being the terminus of a line of railway connecting it with Rostof on Don.

A little to the north of Vladikavkaz, on the Rostof line, lies the group of inland watering places which have long attracted crowds of visitors every summer by the fame of their mineral springs. Piatigorsk with sulphurous waters, Essentuki with alkaline, and Jeleznovodsk and Kislovodsk with ferruginous and acid waters respectively form the chief centres. At the beginning of the summer a larger number of visitors than usual flocked to the springs, hoping thus to escape the cholera, but, as the epidemic rapidly spread through the Caucasus and approached within a hundred versts of Piatigorsk, there was a sudden panic. People fled in all directions and the watering places were speedily emptied.

In the following table the statistical details of the epidemic are given down to Nov 1st. For these figures I have again to express my indebtedness to the authorities of the Medical Department of the Ministry of the Interior.

Table of the Cholera Epidemic in the Caucasus to Nov 1st, 1892 (Old Style)

Province or Government.	Cases.	Deaths.	PER 100 000 INHABITANTS.		Percentage of deaths to cases.
			Cases.	Deaths.	
Terek*	27 095	13 127	8 833	1 639	48.5
Stavropol	14 802	7 880	2,115	1 040	40.2
Kuban	28 669	15,045	1 911	1,003	52.5
Total for the Northern Caucasus	70,550	35 452	2,390	1 203	50.3
Daghestan	28 467	10 450	8 011	1,743	44.55
Baku	11 164	6,831	1 593	970	61.2.
Kars	2,683	1,203	1 341	601	44.75
Zakataly	958	504	1 308	702	60.0
Erivan	8 039	4 845	1 277	609	54.2
Elizavetpol	9 711	5 034	1 070	632	58.53
Tiflis	5,898	3 032	720	370	52.2
Kutais	470	256	0	3	64.0
Total for the Southern Caucasus	63 225	32,001	1 831	9.3	52.0
Total for the Caucasus	133 781	68 353	2,000	1 063	51.1

* To October 15th

* All the dates mentioned are according to the Old Style

A light coloured liquid motion was passed on the third day, and regularly every day after. The pulse on the first day was 72, second, 80, third, 76, fourth, 100, fifth, 102, sixth, 100, seventh, 90, eighth, 102, ninth, 96, tenth, 90, and then it gradually fell. The temperature was 97° on the evening of the operation, on the second day 99.5°, third, 100°, fourth 99.5°. On the three following days it was normal, and then the day after it mounted suddenly in the evening to 102°, falling next morning to 99°, after which it kept nearly normal till he left the hospital, which he did twenty five days after the operation. The plates were never seen in the stools. The patient has gained greatly in weight, being 9st. 7lb. on admission, now, exactly one year and one month after operation, he weighs 13st. 9lb. There is so far no perceptible recurrence.

Remarks.—Three details which Senn strongly recommends I neglected to do in this case, but as matters have turned out they were unnecessary. One is after the introduction of the plates and before tying the ligatures, to scratch the serous surfaces to be apposed, the second is to anchor the bowel in the vicinity of the junction to the parietal peritoneum, and the third to attach round the place of union an omental graft. One detail, however, which cannot be neglected without fatal extravasation of intestinal contents is to be especially particular to bring the serous surfaces accurately in apposition at the point where the mesentery joins the intestine and where the serous coat of the colon is deficient behind. This I was most careful to do. The last I heard of this patient was that he had run a race with a competitor, and, as in the fight, he was the victor.

Albion street, Hull.

A CASE OF PLEURAL EFFUSION AT THE RATE OF THREE AND A HALF FLUID OUNCES AN HOUR

By W. HALE WHITE, M.D. F.R.C.P.,

PHYSICIAN TO AND LECTURER ON MATERIA MEDICA AT GUY'S HOSPITAL.

THE following case seems to me sufficiently remarkable to deserve record. The patient had ordinary tubal nephritis, together with mitral constriction and regurgitation. There was as is usually the case, some fluid in each pleural cavity. On Dec. 11th twelve ounces of fluid were withdrawn from the left chest, and on Dec. 18th thirty six ounces were withdrawn from the right chest. On Dec. 17th the extraordinary part of the case began. The patient was seized with excruciating pain in the right chest and much dyspnoea. Thirty hours after the first aspiration of the right chest 106 ounces of fluid were withdrawn from it. Especial care had been taken to remove all the fluid at the first aspiration so that the whole of the 106 ounces must have collected in thirty hours. On Dec. 20th (seventy-eight hours after the second tapping of the right chest) 120 ounces of fluid were withdrawn from it. On this occasion also there were extreme pain and dyspnoea, in addition there was great oedema of the neck, which I was inclined to attribute to pressure on the superior vena cava and the enormous quantity of fluid in the right chest, for it subsided quickly when the fluid was withdrawn. On Dec. 22nd (thirty hours after the third tapping of it) fifty ounces of fluid were withdrawn from the right chest, which was not tapped again till Feb. 12th, when thirty ounces of fluid were taken out.

It seems to me that the only possible explanation of this extraordinarily rapid accumulation of fluid is that the patient had thrombosis of her large axillary vein before it is joined by that from the left side. It is not against this view that we saw no enlarged superficial veins or the most important anastomoses between the branches of the axillary veins of the two sides and the large axillary vein and the inferior vena cava are deep-seated in the abdomen, the thorax, and around the spine. Nor is it conclusively against this supposition that no evidence of thrombosis was found post mortem for the patient did not die till eight weeks afterwards by which time all signs of thrombosis might very well have disappeared. She herself had the clinical symptoms of thrombosis of her femoral vein only ten days before her death, and yet the vein was at the necropsy found to be patent. I have often observed that when patients have died no evidence has been forthcoming of thrombosis, although all the signs of it have been present during life, and at a recent meeting of the Pathological Society, at which Dr. Pitt read

a paper on Pulmonary Embolism, Dr. Goodhart and others expressed the opinion that all the evidence of venous thrombosis might so completely disappear that no sign of it can be found post mortem. It seems to me that no other explanation offers itself of this case, in which supposing the fluid collected at a uniform rate, after the first tapping of the right chest that rate was three ounces and a half an hour, after the second one ounce and a half an hour, and after the third about one ounce and a half an hour. It is also quite exceptional for the distension of the chest with fluid to be so rapid as to cause acute pain, and it is no doubt comparable to the severe pain in the calf, felt in acute femoral thrombosis and, like it, is probably due to the rapid stretching of the parts by the fluid, also it must be very rare for the pressure of the fluid on the superior vena cava to cause oedema of the neck.

The following are the details of the case.—A young woman aged twenty two was admitted into Guy's Hospital on Dec. 1st, 1892. She had had scarlet fever when young. She was a waitress at a restaurant, and when going home from her work caught cold. The next day her feet were swollen and the day after her face and eyelids and five days later, feeling ill she took to her bed. The oedema increased, and she suffered from pain in the head and in the loins from vomiting and from dimness of vision. On admission she was suffering from general oedema. There was some ascites. The cardiac apex was in the normal position. The chest was dull behind from the eleventh rib for four inches upwards, and over this area there were all the other signs of fluid. The edges of both optic discs were blurred. She was passing about twenty fluid ounces of urine, 150 grains of albumen, and 100 grains of urea a day. Milk diet and diuretics were ordered.

Dec. 7th.—She was better, the oedema of the body generally was less, but the chest was very dull up to angles of the scapulae.—10th She was ordered injections of pilocarpin and a vapour bath at night, compound jalap powder when necessary and middle diet.—11th Twelve ounces of colourless fluid were withdrawn from the left chest.—12th A systolic murmur was heard to-day at the apex for the first time.—16th Thirty six ounces of colourless fluid were obtained from the right chest. The patient was not so well. The systolic murmur was heard in the axilla, and there was a presystolic murmur also. Particular care was taken to aspirate all the fluid.—17th This evening the patient was suddenly seized with excruciating pain in the right chest together with severe dyspnoea. The right chest was found to be extremely dull, and it was at once aspirated, thirty hours after the last aspiration of it, and 106 ounces of fluid were withdrawn. The fluid must if it collected at an even rate have formed at the rate of three ounces and a half an hour. The patient was much relieved by the aspiration.—18th The patient was better, this evening the air was entering the right lung very well.—19th The air did not enter the right lung at all well but there was no dyspnoea, although the dullness extended up to the fourth rib.—20th At 2.30 A.M. the patient rather suddenly became very dyspnoeic, and 120 ounces of fluid were withdrawn from the right chest. Previously to this oedema about the neck had rapidly appeared and was very marked, as though the superior vena cava was pressed upon but it subsided after the fluid was removed.—22nd Gradually the signs of fluid have returned in the right chest, and this afternoon at 4 P.M. thirty hours after the last tapping fifty ounces of fluid were withdrawn. The left chest has always remained free or almost free, from fluid since it was tapped.—27th The fluid was slowly collecting again in the right chest. It was noticeable that the withdrawal of large amounts of fluid from the chest have been associated with a considerable diminution of the general oedema. During January it was not necessary to withdraw any fluid from either side of the chest. The patient suffered from bronchitis, headache and diarrhoea at different times. She also developed well marked albuminuric retinitis, and towards the end of the month pericarditis.—Feb. 7th The legs have been very swollen lately especially the left in which there is such pain and tenderness over the femoral vein as to make one very suspicious of thrombosis in it.—12th The dyspnoea has been getting worse the last few days and to-day thirty ounces of fluid were withdrawn from the right chest.—14th The patient was in all respects much worse, sixteen fluid ounces were withdrawn from the left chest.—17th The patient died this evening.

Necropsy.—The kidneys were typical large white kidneys. The heart weighed thirteen ounces. There were three ounces of fluid in the pericardium. The mitral valve was

It will be seen that during the five months from June to October inclusive there were reported 133,781 cases of cholera in the Caucasus, and 68,353 deaths. If to these figures be added those already given for the Central Asian provinces and Siberia, it will be found that the final totals for the whole of Asiatic Russia were 222,956 cases and 115,184 deaths.

It is impossible to enter here into a full account of the measures taken by the Government to check the spread of the epidemic through the Caucasus and so to European Russia. Early in June a large number of circulars were issued by the various Ministers with this object. The majority were general measures applicable to all parts of the country. Of those specially adapted to the local conditions of the Caucasus the most important had reference to the Transcaucasian Railway. On June 12th M. Gratcheff, the senior inspector of railways, was sent to Tiflis by the Minister of Ways and Communications with instructions to form a Commission, consisting of representatives of the line and the local medical authorities. The duties of the Commission were to organise a sanitary service on the railway, to supervise the carrying out of the numerous Government orders for preventing the spread of cholera, and to concert with the local authorities along the line all measures that seemed to be called for to check the epidemic. Before the formation of the Commission the management of the railway had stopped all goods traffic between Tiflis and Baku, and passenger trains were allowed to run only as far as Baladjari, a station thirteen versts from Baku. Additional measures were taken by the Commission. Sanitary waggons were attached to each train, with accommodation for persons taken ill on the journey, provision was made at certain stations for the removal and treatment of such patients, and disinfection was actively carried out on the trains and at the stations. Unfortunately, however thoroughly these measures may have attained their object on the line of railway, this was but one channel by which the infection was being carried. "Like ghosts from an enchanter fleeing," the "pestilence-stricken multitudes" were escaping from Baku in thousands daily, by road and by sea as well as by rail, and it is questionable whether any measures, however active, could have done much to check the course of the epidemic when once the exodus had begun, more particularly in a country where the hygienic conditions are such as they have been seen to be in the Caucasus.

RESECTION OF THE CÆCUM, GREATER PART OF ASCENDING COLON AND FIVE INCHES OF ILEUM FOR MALIGNANT DISEASE OF ASCENDING COLON

By D. LOWSON, CM. ABERD.,

ASSISTANT SURGEON, HULL ROYAL INFIRMARY SURGEON, HULL WOMEN'S HOSPITAL AND LATE EXAMINER IN SURGERY, ABERDEEN UNIVERSITY

MR. CARPENTER, the assistant house surgeon to the infirmary, has taken great interest in this case, and I transcribe largely from his copious notes. The main events of the clinical history of the case are as follows. Seven years ago, when the patient was thirty-three years of age, he took part in a pugilistic encounter with a pugnacious friend at Drypool Feast (a local fair in Hull). After a long struggle he emerged from the dust and din of battle, victorious. Later in the evening, however, he was waylaid and attacked by some friends of the vanquished, and by them he was kicked, bruised and beaten, and lay half dead for some hours. He was quite unable to walk and had to make the best of his way home on all fours, taking frequent rests. It being now late at night, he met no one on the way to render him any assistance, with the exception of a policeman, who threatened to have him locked up. He arrived home at four o'clock in the morning, and for several weeks was confined to bed. He suffered much from pain in the right side, but discovered nothing unusual about his urine or motions. He had no medical attendance. After this he had good health till January, 1890, when he had an attack of influenza. In May of last year there occurred a severe hæmorrhage from the bowels when quite a pint was lost. A recurrence took place in June nearly as profuse. The same month he sustained a fracture of the leg, and in

November he first noticed a swelling in the right loin. I saw him first in consultation with Mr. Hollingworth of this town, when we found a tumour the size of a situated in the right loin. When in the horizontal position the middle of the swelling was in line with the umbilicus, was firm and very movable, and it had lately become tender on manipulation. There was no obstruction, and June the hæmorrhage had not recurred. In appearance patient was very thin, but he had well developed muscles and in former times had been a very strong man. He lived rather freely and taken a good deal of liquor, without being, in his own opinion, a drunkard. The action of the heart was at times very irregular, but at others no irregularity could be detected. The urine contained albumen nor sugar and had a specific gravity of 1028. He was admitted as an in-patient of the infirmary Jan. 16th of this year and immediately put on milk diet with thirty grains daily of β naphthol in the form of a pill. On subsequent consultation, the diagnosis of malignant disease of the colon being given unanimously, I opened the abdomen on Jan. 24th by a vertical incision in Langenbuch's position to the outer side of the rectus. A large mass immediately presented itself, involving the middle of the ascending colon, the cæcum and appendix being unaffected. The tumour was adherent to the colon anteriorly, and this I severed with scissors and ligature. Pushing the colon inwards, I entered the scissors above the level of the tumour through posterior layer of peritoneum lining the posterior wall of the abdomen to the outer side of the great bowel, and ran down to a point opposite the lower end of the cæcum. The bowel could now be easily separated from its bed. It remained to divide the peritoneum on the inner side the colic vessels spread out fan-like to supply the tumour. This was done by tying the serous membrane with five or six successive pieces and dividing distally, —i.e., between the ligatures and colon. The ileum in this incision inclined downward and inward, meeting the ileum as it crossed to join the colon five or six inches above the ileo-cæcal valve. Several diseased glands were in this triangle. The ileum was separated from the mesentery in the same way, and now the greater part of the colon, with the cæcum and four or five inches of the ileum, was free along with the tumour. The time had now arrived at dividing the bowel. Two long Makins' clamps were applied to the colon above the tumour, and between these the bowel was divided as nearly at right angles as possible. The serous membrane of the upper divided end was stitched together by a fine continuous silk suture, and then on invaginating the stitched end, the serous coat was united by a close row of Lembert's sutures. The ileum was also divided, and the edges turned in and sewed by Lembert's suture in the same way. The whole piece of bowel to be removed was now a liberty, and was lifted out of the abdomen with the tumour. There was left a gap in the intestinal canal extending five inches above the lower end of the ileum to nearly the beginning of the transverse colon, and the ileum ending in the cul-de-sac and the colon beginning in the same way, was necessary to re-establish the continuity of the canal. I therefore opened the transverse colon anteriorly, the opening being rather more than an inch long and running the long axis of the bowel. Into this one of Senn's bone plates was introduced with the threads in position—i.e., placed laterally and one at each end. The lateral threads were drawn through the intestinal wall and the end made to come out at the angles of the wound. The ileum was treated in the same way and a second bone plate similarly introduced. One of the lateral threads of the plate in the colon was united to the corresponding lateral thread in the plate in the ileum and tied firmly a couple of sutures being introduced on each side of it. The end sutures were next knotted, and finally also the other two lateral threads, the whole being rendered more secure by the introduction of a few stitches in the intervals. The parts were gently washed, the clots and sponges removed, the bowel replaced and the abdominal wound closed, a Keith's tube being kept in for a couple of days.

After the operation the patient lay collapsed for several hours. The sickness was at first severe and much pain was complained of. One-sixth of a grain of morphia was given the same evening and one-sixth the next morning. Next day he was better, and would have had very little pain had it not been for a troublesome cough. For two days he had nothing but hot water by the mouth. On the third day he had eight ounces of hot milk, and on the day after two pints

INTUSSUSCEPTION OF THE BOWELS TREATED BY INFLATION

By C. E. SOULBY, M.D. BEUX, L.R.C.P. LOND. M.R.C.S.,
LATE HOUSE SURGEON TO THE MIDDLESEX HOSPITAL.

THE following brief notes refer to a case which I diagnosed as intussusception of the bowels. Of course there can never be any actual certainty of the correctness of such a diagnosis during life unless a laparotomy be performed or the apex of the intussuscepted gut passes out of the anus or can be felt in the rectum, yet, in the following instance, the symptoms seemed to be typical of this complaint.

A bright, intelligent boy of five years was taken ill on Jan. 29th, 1893. He complained of great pain in the body and his parents had noticed a 'lump' there at the seat of pain. During the 27th and 28th he had been troubled with looseness of the bowels the motions at first consisting of faeces, later of faeces and blood, and on the evening of the 28th of blood only. On the 29th I found the boy suffering from great pain in the body, vomiting, a coated tongue, confined bowels and in the right iliac region a sausage-shaped swelling about four inches long very painful when handled. The temperature was normal. I ordered small quantities of beef-tea, milk and ice, and prescribed five-minim doses of tincture of opium. On the 30th the patient was no better, although there was an abatement of the pain especially after the medicine. The bowels were not opened. I examined the rectum, but could feel no intussusception. I kept him on a light diet of beef tea, continued the opium mixture, and in the evening gave a copious injection of warm water. This was of no use and returned in fifteen minutes mixed with dark blood.

Jan. 31st.—His condition is worse. The swelling in the abdomen is increasing in size in a direction upwards and to the left, the abdomen is greatly distended, he vomits more frequently, the tongue is becoming brown, he was delirious during the night, the bowels have not been opened, the pain in the abdomen is greatly controlled by the medicine.—Feb 1st The patient is no better, his condition is about the same as yesterday, the bowels have not acted, the abdomen is still greatly distended. In the evening he had another copious enema of warm water, and afterwards air was continuously pumped in with the Higginson's syringe which I used for the injection of the water. During this injection the boy towards the close, shrieked from pain, and I believe at the time, from what I found on my first visit on the following day, the invaginated bowel was reduced.—2nd. He has had three actions of the bowels since the injection. The first motion consisted of the injection, with some faecal matter and blood, the second of liquid faecal matter and blood, the third of fluid faecal matter only. His condition is entirely changed, the swelling of the body and great distension have disappeared, he has not been sick, and the early symptoms of collapse which were evident on Feb. 1st are passing away. After this he made an uninterrupted recovery, solid faeces passing in due time, the medicine and restricted diet were continued for some days no anæsthetic was used for the inflations. The cause, I believe, is not far to seek for his parents told me that he had for some days previously to the illness been practising "musical drill" with other boys, in which the body assumed many and varied attitudes.

SOME FORMS OF ACQUIRED SPINAL CURVATURE SUCCESSFULLY TREATED BY A MODIFIED FORM OF SAYRE'S JACKET

By M. N. BYRN, B.A., L.R.C.P. IREL. &c.

HAVING had three cases of acquired curvature of the spine under treatment, which occurred in females, all dressmakers, and which had its location in the upper dorsal region, I wish to detail the following case as being the worst of the three.

A young woman aged twenty-one enjoyed good health till eighteen years of age. She left home in the country to live in a town for the purpose of following her occupation as a dressmaker. After a short time she found bending over her work tiresome and complained of a dull aching pain between the shoulders, which developed to such an extent that she had to give up her work and go home, where she remained for

two years and a half suffering great pain, and, to use her own words, unable to lie down, sit or stand with any comfort. Her stature was reduced one inch and a half (from 5 ft. 4 in. to 5 ft. 2½ in.), she was flabby looking, almost unable to walk, and complained of great weakness in the arms, no appetite, and undue prominence of the upper dorsal vertebrae, with redness and tenderness of the skin over them, her chest revealed nothing abnormal on auscultation. I prescribed cod liver oil and syrup of the iodide of iron, and applied the jacket in the following manner. A tight fitting ladies' woollen singlet was substituted for the Cardigan jacket. Outside this I placed a cardboard splint four inches wide, padded with cotton wool, along the spine, and applied the plaster of Paris bandages in the ordinary way. I dispensed with the jury mast Co., the patient being merely standing in as upright a position as possible during the application. In a month she was able to walk with the aid of a stick, and in another three months she regained her full stature, was able to walk about without any inconvenience and entered farm service, where she still remains enjoying good health. The result in the other two cases was equally satisfactory.

HOSPITAL PRACTICE, BRITISH AND FOREIGN

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collatim habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

GREAT NORTHERN CENTRAL HOSPITAL.

GANGRENE OF ANTERIOR FLAP AFTER AMPUTATION
SUBSEQUENT SKIN GRAFTING

(Under the care of Mr PEYTON T. B. BEALE.)

WE have recently had the advantages of Thierch's method of skin grafting after the removal by excision of tuberculous lupus of the skin and subcutaneous tissue brought prominently before the profession at the Medical Society. We now publish notes of a case of a different nature, which will serve to remind our readers that it may be of use in other circumstances. A question which has frequently to be decided by the hospital surgeon when an injury has been so severe as to require amputation of a limb is whether the injury inflicted has lowered the vitality of the tissues near the wound from which he would like to take his flaps to such an extent that they will certainly slough, or not? It is an important question, especially when one of the lower extremities has been injured, for an inch more or less may make the operation successful or unsuccessful in saving life. If the surgeon knows that he may fall back on the use of a process of grafting which will obviate the disadvantages of a contracting cicatrix should a flap slough partially or completely he may feel emboldened to risk this sloughing as it will take place under antiseptic treatment and suppuration with its attendant risks will be prevented. We are left somewhat in doubt, in reading the notes of the case, as to whether Mr Beale would have amputated at the point which he selected finally had it not been for the dictation of the parents, but hold strongly the opinion that before undertaking any operation of emergency the surgeon should be left with a free hand to do what he knows is best for the patient and not accept responsibility with his hands tied.

A boy aged nine was admitted to the Great Northern Hospital on April 19th 1892, suffering from a very severe crush involving the left foot and leg as far as the tubercle of the tibia, also a compound fracture of the right fibula. The laceration of the tissues of the left leg was very great, both bones being fractured in six or eight places. The parents insisted upon the knee-joint being left intact so an amputation was performed at the level of the tubercle of the tibia with the antero-external and postero-internal skin flaps which showed at the time no signs of bruising. Fourteen hours after operation traumatic delirium set in, and the boy's temperature rose to 104. This condition continued, with intermissions, for thirty hours. At the first dressing forty six

both incompetent and constricted. The pulmonary, azygos and left femoral veins all appeared to be normal. The right pleural cavity contained twelve ounces of fluid, the left eight ounces. There was extensive pleurisy over the left lung and some over the right. The bases of both lungs were compressed. There was some pus in both tonsils.

Harley street, W

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL AND THERAPEUTICAL

A CASE OF STRYCHNINE POISONING IN WHICH DEATH OCCURRED AFTER AN UNUSUALLY LONG PERIOD

By THOMAS J HENRY, L.R.C.P. & S. EDIN, J.P.,
GOVERNMENT MEDICAL OFFICER, WARIALDA, NEW SOUTH WALES.

AT 9.35 A.M. on Jan. 27th I was called by the police to see a man aged forty six. He was said "to have taken strychnine to do away with himself." As he lived close at hand I was with him in five minutes. I found him convulsed about the lower part of the body. He told me he had taken, three quarters of an hour or so previously, "as much strychnine as would cover a shilling"—probably from seven to ten grains. He had poured it in a dry state on to his palm, tossed it into his mouth and washed it down with water. He had by threats compelled his wife to watch his actions, and then wait until symptoms manifested themselves—a period of from ten to fifteen minutes. He then sent her to a business man in town with a letter he had previously written, detailing his intention. The woman said she was too frightened to give any alarm, although people lived within twenty yards. She delivered the letter and returned quickly. The recipient of the letter, thinking it might be a serious threat, took it to the police. The latter went to investigate the case and then called me. I adopted the chloral and bromide of potassium treatment, giving large doses of each. I supplemented these by chloroform inhalation occasionally. At first the jaws were free and I was able, by police assistance, to prevent the patient's attempts to bite and got the tube down. I washed the stomach out repeatedly. It was quite devoid of food. He was well aware of the strength and properties of strychnine as he was an experienced dingo poisoner and had over seven ounces of the alkaloid (coloured pink as used in New South Wales) in his possession. To cause more rapid absorption he had refrained from breakfasting and taken a glass of whisky instead. The convulsions were exactly as described in Taylor's and others' works. He complained of great thirst and desired to be placed on his side. About 11 A.M. the symptoms were well marked. I then chloroformed him and he sank into a deep slumber such as chloral would produce, and he remained quiescent and limp till 1 P.M. He then awoke, seemed better, regretted his rash act and even joked. In accordance with the accepted teachings, both of the schools and the textbooks, that after three hours a strychnine patient is practically safe, and, considering the patient's condition, I gave a good prognosis. At 2 P.M. he still seemed improving, but twitchings and mild general convulsions occasionally occurred. I then gave more chloral and at 4 P.M. more bromide. At 3 P.M. I had caused him to be removed to the hospital of which I am medical officer. He was carried the distance, about 200 yards, on a police stretcher, and had no convulsions on the way. About 4 P.M., however, convulsions again became more frequent, and he was much exhausted. What I particularly noticed all through was the extremely sudden cessation of the paroxysms. From the climax to complete relaxation was an instantaneous fall. Each lasted from ten to thirty seconds. There was usually an interval of ten to fifteen minutes between each. At 5.45 P.M. he seemed improving under the treatment, but suddenly as I was speaking to him he said, "Here's another coming" and cried out in terror. A dreadful paroxysm bent him back, he became almost black, and when the sudden relaxation occurred I

found he was dead—asphyxiated by the intensity of the seizure. His pulse continued beating for a few seconds after the respiration stopped.

What I desire to particularly draw attention to is the length of time he lived—eight and three-quarter hours—after the onset of symptoms, or nine clear hours after the dose. Taylor (11th edition, edited by Dr Stevenson) gives six hours as the longest recorded period for a fatal issue, and other works state the same. I think it highly important that it should be known by general practitioners that exceptions may occur in order that no relaxation of treatment may be permitted from a false sense of security.

Warialda, New South Wales

SACRO ILIAC DISEASE, WITH NOTES ON ITS TREATMENT

By PEYTON T. B. BEALE, F.R.C.S. ENG., L.R.C.P. LOND.,
SURGEON TO OUT PATIENTS AT THE GREAT NORTHERN CENTRAL
HOSPITAL, DEMONSTRATOR OF PHYSIOLOGY IN
KING'S COLLEGE, LONDON

SEVERAL points of interest in sacro iliac disease have been recently brought forward in the discussions arising at various societies, and I should like to draw attention to a few facts which seem to show that the disease is often accompanied by tuberculous disease involving the anterior surface of the sacrum. Brief notes of a case which was recently under my care illustrate this point.

A man aged thirty, with a strong tuberculous history, was admitted into the Great Northern Central Hospital in the early part of 1892 suffering from well marked sacro-iliac disease. The disease was of about twelve months' standing, and the patient had undergone the usual treatment—that of opening abscesses and scraping out sinuses—several times. There was complete ankylosis of the left hip, with considerable flexion, dating from the time when the patient was four years of age. When he came under my care there were five or six sinuses in the left gluteal region and over the left sacro iliac synchondrosis, with the usual signs of tuberculous disease of this part. One sinus discharged thick cheesy pus and, when probed, seemed to lead to the great sacro sciatic notch. This sinus was laid freely open until the finger could be passed through the notch. A sequestrum was then felt lying against the front of the sacrum, it could not be grasped or withdrawn even after several attempts with different instruments, nor could it be broken up, as it was quite loose and slipped at once out of reach, so a free incision was made over the situation of the great sacro sciatic notch on the right (sound) side. The left forefinger was inserted and the wound enlarged until the finger passed easily through the notch. By this means the sequestrum was reached, pushed across the front of the sacrum grasped and broken up by forceps, assisted by the right forefinger in the wound on the left side, and the fragments were removed. The other existing sinuses led down to the same region and were laid open, scraped and drained. The shape of the sequestrum showed it to consist of the greater part of the sacro-vertebral articulation and it would appear that the disease had originated in this situation and that the presence of the sequestrum at the front of the sacrum had caused the continuance of the symptoms. In support of this view I may state that Professor Rose had a similar case under his care in King's College Hospital some months ago, where he removed a sequestrum from the front of the sacrum, and other cases have been published where necrosis in this region was described in conjunction with sacro-iliac disease.

Mr. Makins has recently recorded three cases in one of which there was ankylosis of the hip on the affected side. Thus the presence of cervical curies seem to be fairly commonly associated with sacro-iliac disease and both are due to tuberculous affection. The man, whose case I have briefly described improved rapidly after the operation and was able to walk, but he is now suffering from general tuberculosis. I therefore venture to think that in cases of sacro-iliac disease it is of the utmost importance to examine the front of the sacrum through the sacro-sciatic notch, and there is much evidence in recorded cases to show that the disease does exist there, perhaps primarily.

Grosvenor-street, W

and even passed into a status epilepticus. They made apparently complete recoveries.—Dr FRANCIS WARNER asked if mental dissolution in senility was more apt to occur in those of low class mental development. He compared one of the varieties of mental dissolution mentioned by Dr Savage to those cases of defective action of the muscles of the face in which the finer condition of muscle, not to be described anatomically, but known as expression might be left unimpaired.—Dr RICHARDS thought the inordinate appetite of senile dementia might be of local origin and be due to a blunting of the sentient ends of the nerves of the stomach. He did not think that mere absent-mindedness could be regarded as a sign of mental dissolution, for it was often present in young people who were otherwise healthy.—Dr SAVAGE, in reply, regarded the instances related by the President as eccentricities or lapses rather than losses of memory. The cases with epileptiform convulsions were not usually of grave import and they usually occurred in brain workers who had led irregular lives. The degradation of the "higher" mind was more readily perceptible than that of the lower mind. He could not admit the local explanation offered of the cases of inordinate appetite.

Dr FRANCIS WARNER then read a paper on the Constitutional Differences between Boys and Girls and their Relation to Educational Requirements. The statements made were based upon observation of 50,000 children seen by him in schools, of whom 20 per cent of the boys and 15 per cent of the girls were noted as deviating in some respect from the normal. The cases recorded were arranged in four primary groups—as defective in development, in nerve condition, in nutrition, or dull at lessons. It was in the numerical frequency and combination of these states that he sought to indicate the groups of children and the constitutional differences of the sexes. In each primary group except low nutrition, boys predominated. The relative power of resistance to adverse circumstances in boys and girls respectively might be sought in the combined conditions of the "development cases," which were the worst as to nerve and nutrition, with a large proportion of dullness, the boys showing more nerve signs and the girls being more thin and pale and dull. In the worst groups of children, including the imbeciles and those hardly educable, the boys predominated, so also amongst eye cases and for squint. Low nutrition was largely associated with defect in development throughout all groups of schools, this was more strongly marked with girls, increasing under any stress from the environment. Amongst normally made children there was an equal proportion of boys and girls who were pale and thin. Looking at boys and girls as seen in school by the teachers, amongst 100 dull children or 100 nervous ones there were more thin girls than boys. There was a large proportion of boys below the normal make, but amongst abnormal children girls suffered most, the boys appeared to have more spontaneous or uncontrolled growth and brain action, whilst the girls who were below normal in constitution, were more readily affected by their environment. The "development cases" did not appear under as favourable conditions in institutions as in day schools, they grew fatter, especially the girls who increased in dullness more than the boys, whilst the number with disorders of the nerve system was especially increased amongst boys. Comparing children in the upper and lower social classes, the general advantage was with the latter, the proportion with defect in development was equal for girls, but for boys in the upper class it rose, that for "defect in development cases" was for boys more free of nerve signs in the upper class whilst as to the girls they were better off in this respect amongst the poorer class. Hard work seemed to suit the irregularly made boys better than the girls. Amongst the English Irish and Jews, the latter ancient race was the most normal in all particulars whilst the Irish showed the highest deviation from the normal, especially the boys. Dr Warner thought that many of these deviations from normal make of body and action of brain were due to spontaneous growth and action not well controlled by past and present environment—non evolutions or "dissolutions of acquired coördinated action" rather than degenerations on the other hand some defects—e.g., small heads, which were common amongst girls—appeared to be frequent in neighbourhoods with large buildings. Nerve disorder might largely be removed by good training which was particularly necessary for the feebler made children. Whilst school arrangements were framed for average children, it should be remembered that 20 per cent of boys and 15 per cent of girls were found to deviate from the normal, and that

these children, especially the girls, might suffer from want of due attention to their condition, 17 per 1000 of boys and 15 per 1000 of girls appeared to require special methods of care and training. It was suggested that some knowledge of the scientific observation of children should be given to those in charge of schools and that educational methods might be improved by scientific study of children. The efforts of State medicine might well be directed to improving the conditions under which children lived, lessening the proportion with defects and aiding the evolution of a stronger race, well adapted to the conditions under which they had to live. National education appeared to confer great benefits, but great improvements appeared possible.—Dr NORMAN KERR held that our present system of education was wrongly organised. The Jews were examples of the reward that followed strict obedience to the laws of health in body and mind. He looked upon malnutrition as a great cause of mental as well as bodily defect. As much muscular exercise as possible should be coördinated with mental training.—Dr SAVAGE said that if criminal children could be caught young enough they could be prevented from becoming criminals. The deaf and dumb and blind were taught separately and people defective in other ways deserved equal care.—Dr ALTHAUS thought Jewish children more highly neurotic than Christians, and Charcot, who agreed with this, considered it might be due to their earlier persecutions.—Dr SOLOMON SMITH asked Dr Warner whether he had investigated the departures upwards from the normal as well as downwards. Had exceptional brilliancy in boys and girls any relation with abnormalities of development?—Dr WARNER, in reply said that the proportion of nervous cases was higher in the Jew than in the English boy. The great cause of weak and thin children was not want of food but developmental causes which militated against the production of healthy frames.

PATHOLOGICAL SOCIETY OF LONDON

Fibroma of Nose—Anti choleraic Inoculation

An ordinary meeting of this Society was held on March 21st, Sir Joseph Lister Vice-President, in the chair.

Mr G STOKER showed a growth he had removed from the nose of a woman past middle age. There was a history of spitting blood in the morning for three years and phthisis had been diagnosed, though no signs of that malady could be found. In the right nostril a large papillated mass was found springing from the lower border of the inferior turbinate bone, extending back to the naso-pharynx. There was also a smaller mass growing from the middle turbinate bone. Attempts at removal with the cold snare caused nearly fatal hæmorrhage and so the galvanic snare was used. The growth recurred and was removed in October and again in December, but since the latter date there had been no recurrence and the hæmorrhage had almost ceased. Mr Shattock, who had examined the growth microscopically found that it was a Soft Fibroma and the hæmorrhage had come from its deeper part.

Dr E KLEIN read a paper entitled "Anti choleraic Vaccination" an Experimental Critique. The result of the injection of large doses of cholera bacilli (taken from the surface of solidified agar culture) into the peritoneal cavity of guinea pigs produced acute intense peritonitis and death within twenty four hours, which Haffkine and others considered to be proof of the specific action of the cholera bacillus. That this was unwarranted was shown by the facts—(a) that the peritoneal fluid as well as the blood of such animals contained the living bacilli, (b) that the abdominal viscera were greatly congested and covered with pseudo-membranes, (c) that the condition of the intestine was not characteristic of cholera. When guinea pigs were injected intra peritoneally with large doses of agar culture of—(1) vibrio of Finkler, (2) bacillus coli, (3) bacillus of typhoid fever, (4) proteus vulgaris, and (5) bacillus prodigiosus exactly the same disease and the same pathological appearances (intense acute peritonitis) were produced as with the agar culture of the cholera bacilli. The subcutaneous injection into guinea pigs of all these six species taken from agar cultures produced the same local soft oedematous tumour, gradually becoming smaller and firmer and occasionally leading to localised necrosis and ulceration of the skin. Agar cultures sterilised at 62 to 65 C for ten to fifteen minutes and then used for the intra peritoneal or subcutaneous injection of guinea pigs produced the same result in the case of all these six species, but larger doses

hours after operation, the anterior flap showed signs of gangrene, but there was no trace of tension. The whole flap (about three inches long) eventually became gangrenous, and was completely separated on the nineteenth day after operation, the whole process taking place quite aseptically. The raw surface which was left was skin grafted by Thiersch's method on May 25th, all the granulations being shaved off before the grafts were applied. The stump healed rapidly, and by July 8th was quite sound. The boy was seen in January, 1893, and the stump was quite satisfactory in every way. The length of time elapsing between amputation and skin grafting is accounted for by an attack of scarlet fever which commenced on the sixteenth day after admission.

Remarks by Mr BEALE.—This case exhibits the following interesting points (1) Violent traumatic delirium, caused by the large extent of skin lacerated and the great amount of comminution of bone and injury to nerves, (2) the exceedingly high temperature accompanying the delirium and lasting for thirty hours, these two factors bringing about the gangrene of the anterior flap, (3) the sloughing of the flap began and continued quite aseptically, (4) the value of skin grafting by Thiersch's method as applied to a stump. Had this not been resorted to, a second amputation through, or above, the knee joint would have been necessary. I would lay great stress upon the complete removal of all granulation tissue by the knife or razor before applying the grafts as by this means only can the subsequent, and otherwise inevitable, contraction be obviated.

LINCOLN COUNTY HOSPITAL

TWO CASES OF TUMOUR OF THE BRAIN

(Under the care of Dr E MANSEL SYMPSON)

THESE cases will prove of interest to many of our readers, although the symptoms and their mode of development are not fully given. In the first case a primary carcinomatous growth was found in the brain, and there does not appear to have been any secondary tumour in other parts of the body. It cannot have existed for the whole period of the illness. Dr Seguin, in writing of cerebral tumours, published a collected list of 580 in which the nature of the disease was proved, only twenty four of these were carcinomatous, therefore these are rare as compared with tuberculous tumours, which numbered as many as 137.

CASE 1.—A female aged sixty six. For four years she had been suffering from increasing paresis of both legs, attended with great increase in the tendon reflexes. She had for about the same length of time been absolutely deaf in the right ear. She was partially deaf on the left side also. She had double optic neuritis, going on to optic atrophy. She suffered severely from headaches, nausea and actual vomiting, and she was often attacked with dizziness. She eventually sank into a comatose condition for some days before death. On post-mortem examination there was found to be a large tumour occupying the surface of the upper and posterior portion of the temporo sphenoidal convolutions, from the fissure of Sylvius to the sulcus between the second and third convolutions. It was of carcinomatous nature and apparently sprang from the dura mater of the temporal bone.

CASE 2.—A young man aged eighteen was first admitted under the care of the late Mr Sympton into the Lincoln County Hospital on Nov 2nd, 1891, and died on June 21st, 1892. History. He was in the hospital for pleurisy eight months ago,¹ and had pain and swelling in the right hip for three months and pain in the right knee.

On admission there was fullness over the right hip-joint and great pain on attempted movement, the thigh was kept rigid and there was tenderness over the anterior part. He started at night. His leg and thigh were put up in an extension apparatus. The note on March 2nd is as follows: "Tubular breathing over the upper part of the front of the left lung and dulness at the left base behind, caries of the fifth right rib, abscesses over the front of the right femur, left elbow joint and over the third right rib." On May 10th there were complete left facial palsy, diplopia on looking to the left, paralysis of the left

external rectus and double optic neuritis, the urine contained one fourth albumen. He suffered from frequent headaches. There was anesthesia of the cornea and of the left side of the face, the condition of the palate was not tested. On June 19th he was unable to retain any food on the stomach whatever. He died on June 21st from exhaustion. At the post-mortem examination one feature of interest was a dried up empyema which had been detected, watched and heard to disappear during life. In the brain was a tumour about the size of a filbert, in the left side of the pons Varolii, pressing on the floor of the fourth ventricle, especially on the roots of the third, fourth, fifth, sixth and seventh nerves. On being cut into it was commencing to caseate in the centre.

Remarks.—The curiously exact limitation of the tumour and the results produced by its pressure seemed worth recording. It is not often that nature permits her cerebral experiments to be so definite. For the sake of compression no details have been given of the surgical treatment. For the notes I have to thank our late house surgeon, Mr Harper, as well as our present one, Mr D G Watkins, who performed the post-mortem examination in a most careful manner.

Medical Societies.

MEDICAL SOCIETY OF LONDON

Symptoms of Mental Dissolution—Constitutional Differences between Boys and Girls and their relation to Educational Requirements

AN ordinary meeting of this Society was held on March 20th, the President, Dr Bristowe, in the chair.

Dr G H SAVAGE read a paper on the Symptoms of Mental Dissolution. He took as the basis of his paper chiefly his experience of seventeen years at Bethlem Hospital, taking out tables of all patients over sixty, these tables were only useful as general indicators of the way in which senile dissolution showed itself. Herbert Spencer had shown the uses of the study of mental dissolution as well as of mental evolution. Natural decay followed certain lines, but these differed in individuals. Premature decay occurred in certain diseases, such as general paralysis of the insane. It also followed certain toxic conditions, such as those due to alcohol. No single symptom was pathognomonic of dissolution, though loss of memory was the most common. In all stages of dissolution there was loss of mental power, which might be shown in different ways and in different degrees, there might be loss of power or loss of control. Dissolution was shown early by reduced power of acquisition, next by reduction of power of retention of recent impressions, next by defect of coördination, later by loss of control and of judgment. Dissolution was, on the whole, the reverse of evolution, but did not follow quite the same lines. He began by an outline study of dissolution as seen in general paralysis of the insane, next with disorders of control of a general kind such as hysteria, epilepsy, mania, melancholia and dementia. In fact, taking the groups of symptoms before the individual ones, he specially noted the danger of impulse in the maniacal and of suicide in the melancholic states. As to special or individual symptoms sudden loss of memory of recent events, varying much in kind and degree, was most important, loss of emotional control was next in frequency and was even more important as leading to sexual faults. There was a tendency to collect objects of all kinds, which might depend on several causes. There was frequently a disregard of cleanliness which was hard to understand. Judgment might remain for a long time after the memory was weakened and the control defective.—The PRESIDENT related two cases which illustrated a point brought out in the paper. One was that of a well known man, who, in the full zenith of his intellect, while stopping in a provincial town had a standing invitation to luncheon at the house of a friend. One day he went in and lunched, and an hour later returned and asked for lunch again, being apparently unaware that he had already had a meal. In another case a gentleman, who had in the morning made all the arrangements for a conversation and supper party in his house for the same evening came home and went to bed, having forgotten all about it.—Dr PASTEUR referred to cases of men who, between fifty and sixty years of age, suddenly developed epileptic convulsions.

¹ This exemplifies the belief expressed by Dr Barrs of Leeds as to the frequency with which phthisis follows an apparently simple pleurisy. I have seen several instances.

was not entirely sunk in the peritoneal cavity or was made of very thick silk. In conclusion, evidence and experience were in favour of the ligature for general use, as the best method for securing the pedicle when ovarian tumours were removed.

Dr WILLIAM DUNCAN agreed with Mr Doran that silk was by far the best and most reliable substance for ligature of the pedicle. At the same time he would like to point out that one of his colleagues at the Middlesex Hospital invariably uses kangaroo tendon, and with excellent results. He (Dr Duncan) thought that inexperienced operators as a rule used silk much too thick and also employed an unnecessary amount of force in tying. His own plan was to transfix the pedicle with a double ligature of medium Chinese twist which had been boiled in a carbolic solution, and, having divided the ends, to cross them before tying. He had lately discontinued the practice of tying the pedicle twice round and found the results equally good, whilst there was, he thought, less likelihood of the ligature setting up subsequent irritation. It was very important that no traction whatever should be put upon the pedicle whilst it was being tied. He considered that by using sterilised silk and crossing the ligatures there was little to be feared from untoward results, even if a vein happened to be transfixed.

Dr LEITH NAPIER alluded to the practice of covering over the raw surface of a large fleshy pedicle with the peritoneal edges and of securing any prominent gaping vessel with a separate fine ligature as affording additional safeguards from hæmorrhage, from absorption through the raw surface and also from post-operation adhesions to neighbouring parts.

Dr WALTER EDMUNDS said that, though Mr Doran classed complicated knots amongst the causes of disaster and commended a silk ligature with the simplest loop and knot, it must be remembered that these conditions were fulfilled in the earlier cases of hæmorrhage, and therefore the hæmorrhage was the cause of the knots and not the reverse. The reason that the ligature did not sufficiently compress the bleeding artery might be (1) that the loop was loose, (2) that the knot had become undone, or (3) that the pedicle had slipped out of the loop. The loop might be loose because the elasticity of the pedicle had distended the loop after the first hitch only had been tied when the ends of the ligature were relaxed (as they must be) to complete the knot. The difficulty could be met by using two ligatures side by side and tying and drawing tight the first hitch on each simultaneously, by which means the resistance to distension would be much increased, or one ligature could be held tight whilst the other was tied. The knot might come undone by the ends being cut too short or by the ligature breaking as the knot was completed. The boiling of silk in an antiseptic solution materially weakened it and made it advisable before using it to test it, not merely by pulling on it, but by tying a knot on it and then pulling. Lastly the pedicle might slip out of the loop, which might be due to its having been cut too short or to the loop being too loose or to the ends of the knot having been pulled upon, to prevent that it was advisable to cut off the ends as soon as the knot was tied.

Dr HEYWOOD SMITH said that after the first tie of a knot had been made it was very important not to put the least strain on the ends whilst the second tie was being made, as the slightest pull made the hitch likely to slip. He asked Mr Doran if any observations had been made as to whether patients who had had the uterine appendages removed were more liable to phthisis and cancer. He had had a case a few years ago where the patient died within two years after such an operation, and in whom there were no apparent symptoms of phthisis previously.

Dr HERBERT SPENCER agreed that silk was the best material for ligature of the pedicle. Hentsch had shown that chronic gut was undissolved after eighteen months and he (Dr Spencer) had found the silk ligature embedded in adhesions one, two and five years after ovariectomy. He thought floss silk greatly superior to Chinese twist, being cleaner, less liable to be damaged by manufacture and it could be tied tighter. In thick pedicles the first cross of the knot should be nipped with forceps whilst the second was being tied. He had never had a ligature come away afterwards.

Dr BOXALL pointed out that it was necessary to take into consideration the friability of the tissues of the pedicle when selecting the material for ligature. A thin ligature cuts through friable tissues like a sharp knife.

Dr LEWES referred to the shortness of the pedicle as an occasional reason why a ligature could not be securely tied.

In a case of this kind he had left a pair of Well's large pressure forceps on the pedicle for forty eight hours, with a satisfactory result.

Mr DORAN, in reply, agreed with Dr William Duncan in preferring silk ligatures to kangaroo tendon. A silk of moderate thickness made a good deep groove directly it was pulled tight, then the ends might be brought round once more. Boiling silk rendered it liable to snap. He found that sterilised silk was best preserved in carbolic acid mixed with oil of juniper and ready mounted on reels. Transfixion of a vein was a distinct danger. He had known fatal phlebitis with abscess in the pedicle after that accident. He agreed that large gaping vessels should be secured, but after ligature of the pedicle it was usually sufficient to fix a pressure forceps to the mouth of the vessel and leave it there till the closure of the abdominal wound. The application of the forceps, one at each end of the pedicle, and the sinking of the pedicle, the ends of the ligature being cut short at once after the tying of the knot, was the right practice. Dr Edmunds was perfectly right in condemning the opposite practice of leaving the ends of the ligature uncut and pulling on them so as to raise and inspect the pedicle at the end of the operation. He (Mr Doran) found a double reef satisfactory and agreed as to the dangers of a second transfixion where the two outer ligatures pulled on the third between them. He recommended the study of the article on "Knots" in the "Encyclopædia Britannica." One class of knots was made to resist traction from outside its loop, as in the case of a rope cable used in the mooring of an old 100 gun ship, but in securing the pedicle resistance to pressure from within was needed, hence the knot had to be tied on a different principle. He did not like the Staffordshire knot, as the loop had often to be drawn over a broken down tumour and the silk might be contaminated by colloid material, malignant cells, pus, dermoid tissue or other impurity, besides he had known it to slip and it was too complicated. He was not aware that phthisis ever followed as a result of ovariectomy, but he had known a fragment of the wall of a perfectly simple ovarian cyst to undergo malignant degeneration. He had not found, like Dr Boxall, that moderately thin ligatures cut through the pedicle of inflamed appendages. The clamping of the pedicle with large pressure forceps rendered the tissues thinner, yet tougher, and able to resist firm ligature. He was glad to hear of Dr H. Spencer's experience with floss silk and hoped that his drawings of the microscopical appearances of old pedicles would be published. He (Mr Doran) had had the misfortune to see two cases of slipping of the ligature with fatal results, and he believed the fault lay in the tying and neglecting to secure the ovarian vessels separately. He had never lost a patient from this accident, though he had known the ligature to slip before the end of the operation and to require readjustment. Fortunately he had secured the ovarian vessels, otherwise a serious amount of blood might have been lost.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY

Exhibition of Cases and Specimens

THE meeting on March 3rd was devoted to the exhibition of clinical cases and specimens the President, F. Swinford Edwards, F.R.C.S., in the chair.—THE PRESIDENT showed (a) a case of extensive disease of the hard and soft palate in a man of middle age. The mucous membrane was affected on the right side, being much thickened and indurated. There was an enlarged gland beneath the angle of the jaw, and the case was regarded as probably malignant. (b) A case of successful wiring of the patella for fracture. The patient had made a good recovery and was rapidly regaining power of movement.—Dr ABRAHAM showed a man, aged thirty, who displayed well marked signs of Leprosy. He had resided in India till 1874 and it was not until 1884 that the first indications of the disease were observed. The skin of the face, hands and arms was thickened and nodular, and examination of an extirpated nodule showed the presence in swarms of the characteristic bacilli. During the eight years that he had suffered four children had been born to him.—THE PRESIDENT drew attention to the debated question of a fish dietary as a cause.—Mr POTTER asked whether there had been enlargement of the glands or blood extravasations.—Dr MUNRO doubted whether an incubative period of forty years, as reported in some cases, was possible. He

had to be used than of the living bacilli. Guinea pigs which had survived the results of the intra peritoneal injection of non fatal doses of the six species were refractory against a second intra peritoneal injection of otherwise fatal doses not only of the same but also of the other species. Thus guinea pigs which had survived a first intra peritoneal injection of the living or sterilised vibrio of Finkler, of the bacillus coli, or the bacillus prodigiosus, respectively, were found refractory against the peritoneal injection of otherwise fatal doses of the living cholera bacilli of ordinary cultures as well as of the "virus fort" of Haffkine. Similarly the repeated subcutaneous injection of the cultures of the sterilised or living vibrio of Finkler, of the bacillus coli, or bacillus prodigiosus, respectively, protected guinea pigs against the intra peritoneal injection of the living cholera bacillus, even of the "virus fort" of Haffkine. The conclusions drawn from these experiments were 1. The experiments on the guinea pigs made by Haffkine with the cholera bacillus were in no way of a specific character. 2. All the above six species contained in their cell substance the same poisonous material, as was proved by their producing the same illness, the same pathological appearances and acting mutually protectively. 3. This intra-cellular poison must be carefully distinguished from the toxins, albumoses and ptomaines formed by the different species in the nutritive media, including the animal body, whilst the intra cellular poison might be the same in a variety of species (e.g., in the above six species), the specific toxins formed by them in nutritive media were different for the different species. 4. A protection produced by a first injection of the intra cellular poison against a second injection of an otherwise fatal dose of the intra cellular poison was not a protection against the specific toxins, as a matter of fact, guinea pigs protected against the intra cellular poison of the cholera bacilli succumbed after intra peritoneal injection of the toxins produced by the cholera bacilli in gelatine cultures.—Dr WOODHEAD said that some of the experiments related confirmed, whilst others went against, the statements that had been made by Haffkine and other workers. As regarded the results produced by these bacilli, there was one feature present in all the experiments which he had seen conducted—namely, a very large effusion of fluid into the small intestine, he thought that perhaps Dr Klein's animals had escaped this because they had died too rapidly. In some cases the fluid in the intestine was mixed with food whilst in others the fluid was clear containing a few cells only. He had noticed that the bacilli had become altered in these experiments, becoming thicker and comparatively straight, but the same thing happened to those left in the culture tube for a further twenty four hours. He did not think that the evidence was yet sufficient to prove that the poison in all was identical, at any rate, the other results produced by these poisons were not identical. In connexion with this it should be remembered that inoculation of saprophytic anthrax would protect against ordinary anthrax, but that the pathogenic results of the two were not the same. The amount of the dose to produce a lethal result depended to a certain extent on the weight of the animal.—Dr SIDNEY MARTIN insisted on the fact that many substances, some of them vegetable, would when inoculated produce a copious exudation of serous fluid into the gut, these poisons were excreted by the intestinal tract. In regard to the chemical part of the paper he much doubted if the intra cellular poisons were all the same. In diphtheria there appeared to be at least two poisons. One was apparently the primary excretion of the bacillus—it was not a soluble chemical product and acted in extremely small doses, it might or might not be a ferment. The second poison was a soluble product formed from the tissues themselves by the action of the primary excretion. He thought that the comparison with tuberculin was not quite fair, that substance was remarkable from a pathological point of view in being the first body ever produced in a liquid form. It would select local foci of disease for its specific action, it might turn out to be an intra cellular by night. His opinion was no part in the production of tuberculin. The note on the upper part of the paper surprised at Dr Klein's conclusion that one of the bases behind, against another, and would hesitate to call it "vaccination" probably in the direction Dr Martin had suggested. It was a condition of extreme

for a certain time antagonistically to the poison of cholera, but this did not imply that complete immunity was produced.—Sir JOSEPH LISTER said that the announcement was startling one, that bacteria of different kinds should be able to protect an animal against Haffkine's most potent when introduced into the peritoneum. If this were so it was an interesting pathological fact, and it would be an interesting practical one if it could be applied. He asked if, when the animal was inoculated with, say, bacillus coli, the protection still extended to it, even though Haffkine's virus was introduced into the intestinal canal.—Dr KLEIN, in reply, said that he had not been able to demonstrate any relation between lateness of death and fluid in the intestine, though the sooner the animal died the less fluid there was in the peritoneum. He could not be sure that the poisons were identical, but the appearances produced appeared to him to be so. The different organisms might possess similar protoplasmic substances, which would act as poisons when introduced into an animal, but the later metabolism of these substances might be different. The terms he had used were meant not in a chemical but in a bacteriological sense. By "vaccination" he meant the production in an animal of a condition which enabled it to resist a dose of poison which a control animal could not resist. He had found that, under certain limits, the longer the test inoculation was delayed the more pronounced was the refractoriness of the animal. This showed that the toleration produced did not wear off quickly, and this, to a certain extent, weighed against Dr Martin's hypothesis.

The following card specimens were shown —

Mr C SLATER (for Dr BEAVER LAKE) The Organs of a Guinea pig Inoculated from the Lungs of Lepers

Dr LEE DICKINSON (1) Stenosis of the Left Bronchus caused by Dilatation of the Left Arterie, (2) Aortic Aneurysm bursting into the Left Bronchus, (3) Simple Gastric Ulcer unusually situated

Dr VORLOCKER Ulceration from Gall bladder into Duodenum and Transverse Colon

OBSTETRICAL SOCIETY OF LONDON

Exhibition of Specimens — Ligature of the Pedicle in Ovariectomy

A MEETING of this Society was held on the 1st inst., Dr Herman, President, in the chair

The following specimens were shown

Dr MCCLEAN Bones from a case of Extra uterine Gestation

Dr SPENCER Three Separate Placentae from a case of Triplets.

Mr ALBAN DORAN Several specimens showing the condition of the Pedicle at different dates after Ovariectomy

The incoming President (Dr Herman) then delivered his inaugural address after which

Mr ALBAN DORAN communicated a paper on Ligature of the Pedicle in Ovariectomy. A case was described where the patient died of phthisis eight years after ovariectomy had been performed by the speaker. Experience had, he said, justified the opinion of some of the earlier ovariectomists that the ligature is the best method for securing the pedicle. China twist silk should be used, and it should not be too thick or too thin to make a good deep groove in the pedicle when tied firmly. The simplest loop and knot were the safest. The outer border should always be secured separately whenever the pedicle is broad or short and in long pedicles where the ovarian vessels are large. The early union of the tissues bulging over the ligature was well known. The absorption of the ligature had been authenticated by Drs Ballance and Edmunds, who, in a case where the patient died eighteen months after ovariectomy, discovered the knot only of the ligature, the loop having been absorbed. The gradual destruction of the silk by leucocytes getting between the fibres had been plainly demonstrated in the case of arteries. The ovarian pedicle was still better placed to allow that process to go on undisturbed. Alleged disadvantages of the ligature were mostly due to its unskilful application and rough handling, or to the silk being too thick or complicated by knots. The pedicle of an ovary and tube removed for chronic inflammatory changes was less favourable for ligature than was the pedicle of a cystic or solid tumour of the ovary. An analysis was given of cases quoted in text books and elsewhere to show the supposed disadvantages of the ligature. In some the pedicle was not that of an ovarian tumour, or the ligature

2. That in purely sensory nerves stretching is at best but a temporary expedient, and either should not be undertaken or, if having once been performed and followed by a return of pain, should not be repeated. 3. That the reasonable treatment in trifacial neuralgia of an extreme character is neurectomy and that, whilst the operation on divisions of the fifth nerve external to the cranial cavity may be regarded as an established procedure, the ultimate operation of removing the Gasserian ganglion must still be regarded as on its trial. 4. That avulsion should only be practised as a part of an open operation, and that, as originally proposed by Professor Thiersch, it should only be undertaken when an open operation is for sufficient reasons impossible or in expedient.—Mr SWAN confessed that it appeared to him that until the seat of the lesion in the nerve could be accurately localised it was to some extent working in the dark to remove any part of it on the chance of curing a neuralgia.—Mr BROOKS had a similar case under his own care. It was that of a man forty eight years of age, whose superior maxillary division of the fifth was affected for over seven years. He had tried a good many remedies with only transient relief. He found the bony wall much thickened and denser than usually met with in the dead subject. This, he thought, bore upon the observation made by Mr Swan as to the localisation of the seat of disease. Here the pain was localised in the terminal branches of the nerve about the incisor and canine teeth which are supplied by the anterior dental nerve. Consequently it was evident that the lesion of the nerve did not go back to the foramen rotundum. He believed that it was impossible to remove the entire Cæsarean ganglion without opening the cavernous sinus.—Mr FRANKS did not think, in stretching a nerve, that it made much difference whether the nerve was sensory alone or sensory and motor combined. He had seen great benefit from stretching the sciatic nerve in the manner introduced by Bulroth.—Mr STOKER, in reply admitted the importance of accurate diagnosis, but he did not think the situation of pain a definite indication of the portion of nerve engaged. He did not think there was any danger in removing the nerve behind the sphenopalatine ganglion.

SECTION OF OBSTETRICS

Specimens—Case of Spina Bifida successfully treated with Iodo glycerine—Abdominal sections

A meeting of the Section of Obstetrics was held on February 3rd, Dr Atthill in the chair.

Mr GLYNN exhibited for Dr W J Smyly a specimen of Sarcoma of Uterus. The patient, aged sixty was admitted in January and curetted, the scrapings were examined by Dr Earl and pronounced to be sarcoma. The patient left the hospital, and for domestic reasons was unable to return for a month. On examination a polypus was found projecting from the os, which was removed and sent to Dr Earl, who reiterated his former opinion. The patient suffered very much from profuse hæmorrhage. On Feb 3rd vaginal hysterectomy was successfully performed. Mr Glynn also brought forward a case of Double Ovariectomy. In this case the right ovary was easily removed, but the left gave trouble, being strongly adherent to the descending colon. Recovery ensued.

Dr ALFRED SMITH showed tubes and ovaries which he removed from a patient, aged thirty four, who suffered from a bleeding Fibro-myoma of the Uterus. As a preliminary treatment he curetted away the fungous endometrium the week previously to the operation. The patient was doing well.—Mr MCARDLE wished to know the relative mortality on the removal of fibroids as compared with that on the removal of the ovaries.—Dr SMITH in reply said that in laparo-myotomy the mortality was 1 in 4, whilst in removal of the ovaries and tubes for myomas it was roughly 1 in 10 or 1 in 15.

Mr McCULLAGH then read a paper on a case of Spina Bifida successfully treated with Iodo-glycerine. The child—a male now five years and two months old—was not brought under the notice of Mr McCullagh until it was ten months old. There was then in the lumbo-sacral region an ovoid tumour four inches long three broad, and elevated from two inches and a half to three inches over the surface, the long axis of the oval corresponding to the vertical line, it was sessile translucent, marked with white bands, fibrous in character coinciding with depressions on the surface of the tumour as if they constricted it. Mr McCullagh, having determined to operate, selected the operation best known in connexion with the name of Dr

Morton—namely, after the withdrawal of some of the sub-arachnoid fluid, the injection of a solution of 10gr iodine with 30gr iodide of potassium in an ounce of glycerine for the purpose of exciting local inflammation. This operation however, he modified, finding the withdrawal of the fluid was followed by a convulsion, he found that he obtained quite as much flaccidity in the tumour by laying the child on its face, with the hips raised. Next he found that where he had made the injections completely through the coverings of the tumour the effect was either *nil* or only slight circumscribed meningitis, whereas in those injections where the penetration was not perfect, as at the margins and the white fibrous bands already mentioned, small patches resembling the islands in skin grafting were produced. He therefore confined himself altogether to dealing with the bands and the edges of the tumour, with the result that the whole tumour was soon covered. He then ceased the injections and painted the surface over with a double strength solution with the result that the covering thickened and soon assumed the indurated condition which was present when the members saw the child exhibited. Mr McCullagh's conclusions were 1. That the subsequent meningitis developed in many cases treated by iodo glycerine was due to the intra saccular injections. 2. That neither they nor the preliminary evacuations of the contained fluid are necessary. 3. That Dr Morton's method as modified is not only incomparably safer, but gives a result as good as could be hoped for from the most successful plastic operation.—Mr MCARDLE referred to a case which he himself had exhibited of large spina bifida, which recovered spontaneously, but only after a long and painful illness. He said that the treatment which Mr McCullagh had so successfully carried out was certainly devoid of any element of danger.

PROVINCIAL MEDICAL SOCIETIES

BRADFORD MEDICO CHIRURGICAL SOCIETY.—A meeting of this Society was held on March 7th, Dr J H. Bell, President, in the chair.—Mr HORROCKS read notes of a case of Ectopia Vesicæ, which he had studied by means of frozen sections. He described the anatomy of the malformation, which he regarded as due to failure of the closure of the urachus at the umbilicus.—Dr GOYDER gave his experience with Salol, which, he said, is not absorbed from the stomach, but split into its two components in the intestine, salicylic acid being excreted in a combination in the urine. It was not so useful as an anti rheumatic as it was as an intestinal and urinary disinfectant, he particularly used it in cases of pseudo-dysenteric nature and pyelitis.—Mr ALTHORP read notes of the case of, and showed the Bladder, from a man aged seventy-seven, who suffered from enlarged prostate and calculus. Sixteen years ago he had had lateral lithotomy performed and a 164gr calculus removed. Later lithotomy was practised, and six months after that lateral lithotomy again and a 184gr calculus was removed. He had not been well after, and three months ago a calculus was removed by the supra pubic method, prostatectomy was deemed inexpedient. He did well till the seventeenth day, when, without fever, delirium set in and lasted till death on the twenty eighth day.—Dr ADOLF BROXNER read a paper on Disease in the Naso-pharyngeal Cavity. He insisted on the permanent effects of even passing disease.—The following specimens were exhibited: Broad Ligament Ovarian Cyst, removal followed by melan cholla, Dilated Tube from Chronic Salpingitis, Tuberculosis of Urinary Tract and Heart from case of Ulcerative Endocarditis, Preparations from Spinal Cord in Myelitis.

MANCHESTER MEDICAL SOCIETY.—At the meeting of this Society held on March 1st, Mr F W Jordan Vice-President, in the chair. Dr MILES made some remarks on Acute Tonsillitis in its relation to Rheumatism, illustrated by references to the clinical history of a number of cases. As regards treatment, full doses of tincture of perchloride of iron every two hours, with wine to adults and avoidance of exposure to any chill proved most successful, and since adopting such measures Dr Miles had never met with rheumatic sequelæ.—Mr F A. SOUTHAM drew attention to the operation of Supra pubic Cystotomy and mentioned a number of cases to illustrate the different conditions in which the operation was indicated.—viz. (1) For the removal of tumours of the bladder, (2) in cases of calculi where lithotomy was contra-indicated by the large size of the stone, or its encysted position, or when associated with enlargement of the prostate, (3) in cases of prostatic retention where palliative

considered it remarkable that the patient should have progressed since he had been suffering from the disease, the testicles, as a rule, being early affected and sterility resulting. He regarded the fish theory of causation as absolutely without foundation.—Dr MORGAN DOCKRELL referred to the fact that sexual appetite was, as a rule, not wanting in lepers, though power of propagation was impaired.—In reply, Dr ABRAHAM said that glandular enlargement and extravasations were absent in this case. He, too, thought that a fish diet had no causal connexion with the disease.—Mr BIDWELL showed a lad, aged nineteen, in whom a compound comminuted fracture at the lower end of the humerus had been caused by the crank of a steam engine. On his admission to the West London Hospital there was found a contused wound about three inches long on the outer side of the arm and a smaller one on the inner side, the skin and surface of the wounds were covered with engine grease and dirt, and some fragments of bone were lying loose in the wound. Three or four of these were removed and the ends of the bone united with silver wire. The edges of the wound were freely pared, and after irrigation with perchloride of mercury solution were brought together with silk suture, no drainage tube being used. Cyanide dressings were employed and the limb enveloped in plaster of Paris. It was not dressed for a fortnight, and then both wounds were found to have healed by first intention. The splint was left off at the end of a month, and the movements of the arm are now perfect.—A patient under Mr BIDWELL'S care, a man aged sixty, suffered from Epithelial Crypts of the Palm. On the left hand a probe could be passed a quarter of an inch into one crypt, here there was also some Dupuytren's contraction opposite the fourth finger. On the right hand the opening was much smaller, a little swelling could be felt and a fine probe passed in half an inch. Here there was no Dupuytren's contraction. They were painless, and patient did not know how long they had existed. Mr Bidwell suggested as a possible cause that during his work of bricklaying some slight injury might have been done to the skin, epithelial cells being driven in and forming an epithelial tunnel. He compared them to implantation "dermoids".—Dr BATTER and the PRESIDENT considered the Dupuytren's contraction a more probable cause.—Mr R. LAKE showed a case of Lupus of Larynx, Pharynx and Soft Palate. The epiglottis was almost destroyed and the right ventricular band was affected, though the vocal cords still remained free. The case was of two years' duration and had at one time improved under a saturated solution of lactic acid. The present local treatment consisted of aristol and salicylic acid.—Dr CLIPPINGDALE showed a young girl who presented numerous small flattened sessile Epithelial Nodules on the skin of the forehead, chin and forearms, which had existed since last September.—Dr ABRAHAM regarded the growth as of a warty nature.—Mr KEETLEY brought forward a case for diagnosis. The patient was a young girl, and presented a growth apparently beneath the fascia in the muscles of the forearm. It was oval in shape, about two inches and a half in length and rather less in breadth, soft and giving to the touch an obscure sense of fluctuation. Mr Keetley said he had come to no definite conclusion as to its nature, but intended to cut down upon it with a view to its removal.

ROYAL ACADEMY OF MEDICINE IN IRELAND

SECTION OF MEDICINE.

Some Points in the Treatment of Phthisis—Clinical Experiences

A MEETING of the Medical Section was held on Jan. 27th, Dr H. Benson in the chair.

Dr WALLACE BEATTY exhibited two patients, both being females with Lupus Erythematosus.

Mr DENHAM then read a paper entitled "Some Points in the Modern Treatment of Phthisis".—Dr NIXON said that cases of phthisis amongst the poor might be divided into those which were curable and those which although incurable, might be relieved as regarded the most distressing symptoms and have their lives prolonged. The cases coming under the first class were very few. There was not a sufficiently good combination of circumstances as regarded climate to give them a favourable chance of recovery whilst resident in Ireland. The second class of cases could be well treated in the wards of a general hospital.—Dr J W

MOORE differed from Dr Nixon. He thought the climate of Ireland fulfilled all the desiderata for the treatment of phthisis which were asked for by Dr Nixon, and with the single exception of humidity, more so than any other place. He thought that patients belonging to Dr Nixon's second class should not be admitted to a special hospital whose object was to give those who had a fair prospect of cure a chance. These patients could be received into the Royal Hospital for Incurables or into the Hospice for the Dying. In the proposed new hospital each patient would have a separate sleeping apartment.—Dr NINIAN FALKNER thought that cases of phthisis should be removed from crowded tenement rooms, and if this were done the death rate from phthisis would be lower.—Mr DENHAM, in replying said that when he commenced to investigate the subject of the new hospital he was strongly prejudiced against it, but that as he proceeded in the study of the subject he became a firm believer in it. He thought ordinary hospitals were defective for treating phthisis in the following points. First, the temperature was not constant, secondly, the cubic space allotted to each patient was insufficient, and, thirdly, the diet was unsuitable. He thought the patients suitable for admission to the new hospital would be those in whom the physical signs were not marked. He repeated the decision of the tenth Medical Congress held at Berlin, which was strongly in favour of treating pulmonary phthisis in special hospitals.

Dr J W MOORE detailed notes of a series of five cases selected from those which had come under his observation during a recent period of clinical duty at the Meath Hospital, lasting from Oct 1st to Dec 31st, 1892. Whilst they were, no doubt, types of the every day clinical experiences of a hospital physician, the cases threw more or less light upon obscure features in diagnosis and pathology, and illustrated some practical points in treatment. Hence their selection. They were as follow—(1) Axillary abscess in an infant simulating scarlet fever, (2) septic peritonitis from rupture of a small ovarian abscess, (3) retro pharyngeal abscess in a man aged forty five years, (4) a case illustrating the short incubation and invasion of scarlet fever, (5) thoracic aneurysm perforating the pericardium.

SECTION OF SURGERY

Splints—Operative Treatment of Trifacial Neuralgia

A meeting of the Surgical Section was held on Jan 20th, Mr Hamilton, President, in the chair.

Mr HERCULES MACDONNELL read a paper on Splints, showing a modification of Liston's long splint and of the box splints for application to fractures of the leg, and claimed, from a long experience, advantages from those splints.—Mr THOMSON said that he preferred the simpler and less expensive plaster splint to any elaborate appliance.—Mr MACDONNELL admitted the efficiency of the plaster splint, but said that cases arose in which it could not be applied.

Mr THORNTON STOKER read a paper on the Operative Treatment of Trifacial Neuralgia, in which he briefly reviewed the recent work which has been done in this direction, and advocated operation on the fifth nerve in those extreme cases of epileptiform tic which had failed to yield to other treatment and were so severe as to destroy comfort or threaten life. He reviewed the various methods of neurotomy, stretching, avulsion, and neurectomy, and argued in favour of one or both of the latter as the best plan of operative treatment. He decried neurotomy as an uncertain and halting treatment, almost sure to be followed by a return of the neuralgia. He opposed stretching in the treatment of purely sensory nerves, as a mere temporary expedient. The paper dealt specially with cases in which he had removed the infra orbital and gustatory nerves. The operation he advocated in removal of the infra orbital nerve, and which he had performed with a perfect result, was the orbital method of Wagner and he exhibited two instruments he had devised to facilitate its performance—one a retractor to lift the perosteum and contents of the orbit, the other, an instrument to free the nerve from its relations. In removal of the gustatory nerve he had employed the method of Paravacini, which he advocated as much less formidable than the retro-orbitary or transmaxillary operations and as giving sufficient access in most cases—the exceptions being those instances in which malignant disease had so much intruded on the mouth as to render the buccal operation impossible. He concluded 1. That in cases of trifacial neuralgia demanding operative treatment neurotomy is not usually a satisfactory or efficient operation.

Vision," referring to the pitfalls that beset the general practitioner, such as headache from astigmatism, iritis treated as neuralgia &c., and gave a *résumé* of the chief difficulties in this direction and the methods with which to guard against them.

Reviews and Notices of Books.

A Treatise on Public Health and its Application in different European Countries. By ALBERT PALMBERG Doctor of Medicine and Surgery, Medical Officer of Health for the County of Helsingfors in Finland, Vice President of the Hygienic Society of Finland &c. Translated from the French Edition, and the Section on England edited by ARTHUR NEWSHOLME M.D. Lond. D.P.H., Medical Officer of Health for Brighton &c. With 182 Illustrations. London Swan Sonnenschein and Co. New York Macmillan and Co. 1893

This is not only a very useful book, but it is unique in its way, a careful comparison is instituted between the sanitary organisation and practice of different continental countries and those of this country, and information is given on many points of practical detail from which the English hygienist may ascertain the various methods of procedure abroad and compare them with those adopted at home.

The author, in his preface to the English edition, says that the favourable reception of the work has far surpassed his expectations, and that—the original Swedish edition having been already succeeded by a French one—Spanish and English editions have now been asked for. For the purpose of securing a more accurate description of all the details of English sanitary legislation and administration, Dr Palmberg has obtained the aid of Dr Arthur Newsholme, who is actively engaged in sanitary work, to bring up to date and complete the chapter relating to England, especially that portion of it bearing on recent legislation, and we may say at once that this seems to have been thoroughly well done. As regards the general character of the book, it may be stated that its practical spirit is best indicated by the remarks in the author's preface. Public hygiene is perhaps more empirical than are other sciences. The putting in practice of theoretical views has often produced results different from those which were expected. Practice showed that the best way of avoiding the evil results from sewer air was not to hermetically close the sewers but to provide for their good and active ventilation, combined with frequent and abundant flushing. Again, theory speaks against the irrigation of fields by sewage, on the supposition that the pathogenic organisms contained in it, when exposed to the sun, would produce an extensive propagation of infectious diseases. Practice has shown the error of this view, and it is now experimentally proved that irrigation is the most effective method for the destruction on a large scale of pathogenic micro-organisms. The importance of practice is therefore, says the author, considerable in sanitary science, and this "Treatise on Public Health" is based upon his conviction of this truth and of the enormous value of a complete knowledge of sanitary arrangements proved by experience to be good. The description of the sanitary organisation of different countries is mainly based upon official information placed at Dr Palmberg's disposal and appears to be exact and reliable. The sanitary laws, systems and appliances described or referred to include those of England and especially London, Scotland, Belgium, France, Germany, Austria, Sweden and Finland. The subjects of statistics and the importance of public hygiene as shown by the mortality from general causes and from typhoid fever in different countries, mortality in armies and in great cities and towns and cholera in its relation to sanitary organisation, and a good bibliography and index, complete the volume. We should also add that the work is well and even profusely illustrated.

The section on England is, as we have already said in effect, comprehensively and well executed. It is gratifying to notice that this country receives its full meed of recognition and praise, it being said that of all countries in the civilised world none has a sanitary code so complete and precise as England, and that no nation has appreciated so thoroughly as have the English the importance of fresh air. It is declared to be one of the causes which have made the rate of mortality lower in Great Britain than in most continental countries. The chapter on Paris affords a good deal of useful and interesting information. Experiments made in that city fully demonstrate, that if sewers are to be prevented from diffusing bad smells they must be kept free from deposits, carefully ventilated and cleansed. It has been proposed to close the openings in the streets and to employ ventilating shafts for the removal of sewer air. But the author is of opinion that such appliances only act on a small length of sewer, besides being complicated and difficult to manage. Ventilation is most effectually secured, he considers, by making numerous openings of sufficient size. If it is desired to place traps in the openings to the sewers from the pavement, the openings for ventilation must, he says, be placed in the road over the sewers. Speaking of the proposal in England to ventilate the sewers by means of shafts opening above at the gas-burners of the public lamps in the streets, it is remarked that this has not been found advisable, as, when the gas is not burning, the exit of foul gases at such a low level might produce a serious nuisance. A description of the sewage farms at Gennevilliers and D'Achères and their working is given, together with some observations on the action of land upon sewage and pathogenic organisms as deduced from practice and experiments. The land at present used by Paris for the irrigation of sewage covers too small a surface. We had marked quite a number of passages for quotation or reference, but to collate and pass in review even a small number of the facts and observations comprised in this volume would extend our notice to too great a length. We trust that we have said enough to show that, in our opinion, it is a most useful work, and especially valuable to the English hygienist who desires to ascertain and compare the various methods of sanitary procedure on the Continent with those in use in this country.

The Chemical Basis of the Animal Body an Appendix to Foster's Text book of Physiology. By A. SHERIDAN LEE, F.R.S., University Lecturer in Physiology in the University of Cambridge. London Macmillan and Co. 1892. Pp. 290.

A WORK like the present was much needed. The last really good text-book of the physiological chemistry of the animal body was written by Professor Arthur Gamgee, and was published in 1880. Twelve years have therefore elapsed since the appearance of that work, during which time much has been done, and it required a competent teacher to collect the facts that are distributed through many journals and to present them to the student in a readable form. The bibliography, which is copious, includes references to a very large number of the papers recently published in Hoppe Seyler's *Zeitschrift für Physiologische Chemie*, Pflüger's *Archiv* and the French and English journals of *Anatomy and Physiology*, and is consequently brought well up to date. It differs from Professor Gamgee's work in that it deals only with the chemical constituents of the body, and does not pretend to give the full description of the chemical composition of the various fluids and solids of the body—such, for example, as the blood, gastric juice and urine,—though their chief constituents are separately discussed. The plan pursued is that in the first instance the proteids are classified and their chemical characters given, the group being divided into seven classes. Native albumens, derived albumens, globulins,

treatment failed to afford relief and self catheterism was impracticable either as a means of draining the bladder or with a view to prostatectomy, (4) in obstinate cases of chronic cystitis, especially when tuberculous—Mr WALTER WHITEHEAD read a paper on Aseptic Details in Surgery—At the meeting on March 13th, Mr F W Jordan Presided, and Dr WHITE related the case of a man who, whilst repairing a strap which was lying loosely round a revolving shaft, had his hand carried between the strap and the shaft, causing Dislocation of the Lower end of the Ulna forwards. The symptoms were—extreme narrowness of the forearm, as though both bones had been pressed close together, the hand in a state of moderate supination, rigidity of the wrist-joint, absence of usual prominence of the ulna and in its stead a great gap. The head of the ulna could be seen and felt lying upon the front of the lower extremity of the radius, the radius was in its normal relation with the carpus. Reduction was effected under chloroform by means of powerful extension and counter extension and pressure of the displaced head in the direction of the sigmoid cavity. The forearm was kept in splints for about a fortnight, the bone has shown no tendency to re-displacement, and at the present time (two months after the accident) the limb is as useful as ever. This appears to be the thirteenth recorded case of this injury. Malgaigne collected records of nine cases and Hamilton of three, one of which he saw himself—Mr WHITEHEAD gave an account of a Fibroid Tumour he had recently removed in the Royal Infirmary from the thigh of a youth twenty years of age. The tumour measured eight inches in length and three in diameter. It was detected five months previously to admission as a hard tumour in the popliteal space, extending upwards between and partly lost behind the hamstring muscles. In dissecting out the tumour it was found to be intimately adherent to the popliteal vessels and to follow them upwards to its full extent. Eight inches of the nerves were completely detached from their surroundings during the operation and were ultimately left in an isolated condition in the wound. The tumour apparently originated from the periosteum of the femur, but probably an intra muscular septum might have been responsible for its origin and microscopically it was evidently an ordinary fibroma. The function of the popliteal nerve was not in the slightest degree affected by its disturbance and separation from its natural attachments—Mr Wm COATES and Mr G A. WRIGHT showed a Vermiform Appendix and Fecal Concretion removed by operation from a man of twenty eight who had suffered from seven attacks of recurrent appendicular peritonitis. The patient recovered.

MANCHESTER PATHOLOGICAL SOCIETY—A meeting of this Society was held on March 8th, Dr Judson S Bury, President, in the chair—The PRESIDENT related the history and showed specimens of the following case. A man aged forty one received a blow on the top of the head a year before death. He was unconscious for half an hour, but continued at his work for three months. A few weeks after the blow his sight began to fail and he suffered from headache. Later his left arm and subsequently his left leg became weak. When seen about six weeks before death there was slight weakness of the left limbs, double optic neuritis, mental dulness, and constant right sided headache. He became worse, and a week before death developed complete left hemiplegia and passed into a state of coma. At the necropsy a vascular sarcomatous tumour occupied the first right frontal convolution. The surrounding brain substance and the white matter beneath, particularly the fibres of the internal capsule, presented acute softening. No evidence of damage to the skull was discovered, but a small exostosis was situated just above the middle of the tumour and possibly determined its position if it be allowed that the tumour was started by the injury from the blow—Dr EMERY JONES exhibited microscopical specimens of (a) Sarcoma of the Choroid, (b) Glioma of the Retina, (c) Lupus of the Conjunctiva—Dr ROBINSON and Dr MENZIES showed and described preparations of Brain and Spinal Cord, prepared by Golgi's Method—Dr BROOKE showed preparations from a case of Tuberculosis of the Skin.

SHEFFIELD MEDICO CHIRURGICAL SOCIETY—A meeting of this Society was held on March 9th, the President, Mr Simeon Snell, F.R.C.S. Edin., in the chair, at which Mr PYE SMITH showed two cases of Excision of the Wrist. In one, that of a girl with pulpy disease of the right carpus, without sinuses, of eighteen months' duration all the carpal bones except the trapezium were removed, with parts of the metacarpals and of the radius and ulna, by a single dorsal incision. Passive move-

ments were commenced on the third day and the wound soon healed. Now, three months after the operation, there was remarkably little deformity. The patient could write well and had a very useful hand. The other case was that of a boy with caries of the left carpus, sinuses and swelling of three years' standing, following a crush. It was similarly treated and was resulting in a useful hand, though the sinuses were not yet healed. Mr PYE SMITH also showed a man with a large Hunterian Chancre on the Left Eyebrow. The patient had received an injury there in a scuffle a month before the appearance of the chancre. When first seen, a week later, the chancre was nearly an inch in diameter, there was a hard gland in front of the ears and a faint macular rash on the chest and abdomen—Dr BURGESS read the notes of a complicated case of Heart Disease. In addition to mitral stenosis and tricuspid regurgitation with large pulsating liver there was a diastolic murmur heard loudest in the second left interspace and conducted to the left, but not heard to the right of the mid sternal line nor below the third interspace. The cyanosis, dyspnea, hypertrophy of the right ventricle and tricuspid regurgitation were explained by the mitral stenosis and could not therefore be cited in support of pulmonary regurgitation. The pulse was not decisive, but the fact that the valvular lesions resulted from rheumatic endocarditis was strongly in favour of aortic regurgitation—Dr WILKINSON showed the kidneys and bladder, with a large stone nearly filling it, of a man who died from Suppression of Urine. He also showed several large Vesical Calculi which Mr Thorpe had recently removed by operation—Mr DALE JAMES read a short paper with the view of assigning to diet its proper place in the treatment of Cutaneous Affections. The question of food was doubtless important in acute dermatitis, but chronic skin diseases such as psoriasis did not in his opinion require special dieting. The very variety of diet tables recommended proved that there was no ascertainable rule in the matter—Dr SINCLAIR WHITE read a paper on Hernia in Childhood and showed fifteen children who had been operated on at the Children's Hospital and elsewhere for radical cure. Thirteen of these were cured and two very much improved. Professor MacEwen's method of dealing with the sac was adopted in every case—Dr WHITE advised operation in all children not cured by the careful and continuous use of a truss for twelve months, or where for any reason, a truss cannot be worn. The operation was based on sound principles, it was singularly free from risk to life and gave excellent results.

ULSTER MEDICAL SOCIETY—The fifth meeting of the session was held on March 8th, at the Museum, College-square North, Belfast, the President, Dr Whitaker, in the chair—Dr CALWELL showed a case of Pityriasis Rosea in a woman aged forty six. The eruption began two months ago on the inner side of the right thigh, from which it spread all over the trunk, the face, the neck and the extremities, the parts below the knee and elbow remaining free. The eruption is now characterized by pinkish red rings of varying sizes, gyrate lines, and patches very slightly raised and with slight and rather faint desquamation, the borders are well defined, and the centres of the circles have a faint fawn colour, there is some itching, more especially at night, and the eruption is fainter on the trunk than formally, but is still well marked on the thighs, and a few circles have lately appeared below the knee. It spread all over the body in about two weeks. Little or few constitutional symptoms were complained of, and no fungus was discovered under the microscope. It was evidently the variety pityriasis rosea circinata. He showed two cases of Lupus: one with a very tumid condition of the upper lip, the disease spreading to the gums and palate, the other a very superficial form on the neck. He recommended strongly, where there is no operation the application of carbolic acid and continuous boracic poultices—Dr ST CLAIR BOYD showed a large Multilocular Cyst, which with great difficulty, owing to adhesions from five previous tappings, he had successfully removed from a patient. He also showed the appendages he had lately successfully removed from another patient for hæmorrhage and pain, rendering her life useless and burdensome—Dr W H THOMPSON read a paper on the Physiological Action of Atropine and Morphine on the Secretion of Urine. It was a description of some of his work in the Physiological Laboratory at Leipzig, embracing eleven experiments on dogs. He showed that both atropine and morphine diminished the quantity of urine and the quantity and the percentage of urea, but increased the quantity of nitrogen of other products—Mr CECIL SHAW read a paper entitled "Notes on some Common Defects of

work as the present is nothing if it be not complete. In addition to the kind of information usually to be found in "Year Books," we have here and there articles which may be almost described as essays. Moreover, there is a section devoted to information concerning hospitals and the staffs of hospitals in the colonies, another dealing with institutions of a similar kind in America, and yet another concerned with societies engaged in philanthropic work. Of course, in such a repertory of facts and figures as the one under review errors will occasionally creep in, but, so far as we have been able to observe, inaccuracies are few and far between.

THE *Medical Register* for 1893 was published on the 20th inst. and can be obtained from the General Medical Council's publishers (Messrs Spottiswoode and Co Gracechurch street, E.C.) From the statistics supplied amongst the preliminary matter there will be seen the continued growth of the medical profession. During 1892 no fewer than 1513 newly qualified practitioners registered their names against 1345 in the preceding year, and the total number of practitioners in the United Kingdom, which at the beginning of the year 1876 was 22,200, has now risen to 30,590. This increase in numbers has been attained notwithstanding an average annual death rate of 569 or an average annual removal from the Register, from all causes, of 834 names. Of the 30,590 practitioners whose names now appear in the Register, 18,622, or 60.88 per cent., were registered in England, 7320 or 23.93 per cent., were registered in Scotland, and 4648, or 15.19 per cent., in Ireland. The new Colonial Register, instituted by the Medical Act 1886, now contains fourteen names, representing the Universities of Melbourne, Sydney, New Zealand and Bombay the last of which was recognised by the Council last year in consequence of the extension of the Act to India by Order in Council. The correctness of the Medical Register, so far as it is possible to ascertain it, has been ensured by the thorough revision to which it has again been subjected.

The *Dentists Register* and the *Medical Students Register* for 1893 have been some time published and are now on sale by the same publishers. Advantage has been taken of the issue by the Council of a resolution in regard to "covering" to send to all registered dentists an inquiry form to ensure the correctness of their addresses and qualifications, and, as a result of this inquiry, the information in the *Dentists Register* is more than usually accurate. The total number of names now appearing in this Register is 4817 as against 4896 in the Register for 1892, being a decrease of 79 probably due to the thoroughness of the revision. Of the 4817 registered dentists an increasing proportion are Licentiates in Dental Surgery of the several Colleges, the percentage of such dentists being now 25.43, as against 24.07 last year, showing a marked increase from the 10.74 in the Register for 1881. On the other hand, the percentage of dentists whose names appear with no such qualification has further decreased from 75 in 1892 to 73.49 in 1893—a marked diminution from the 89.26 of 1881. The *Medical Students Register* shows a decided decrease in the number of those who are entering the profession, 734 fewer students registering in 1892 than in 1891, the total number being 1671, which is lower than for any year since 1876. Complete information is furnished as to the various examinations of the preliminary examining bodies on which the students registered and the various medical schools at which they commenced their professional study.

MEDICAL MAGISTRATE—Mr Henry Monckton, M.D. Lond., F.R.C.S. Eng. has been placed on the Commission of the Peace for the borough of Maidstone by the Lord Chancellor of England.

New Invention.

NEW FORM OF BULLET EXTRACTOR.

FINDING that most existing bullet forceps are unsuitable

and unsatisfactory for the extraction of the new compound bullet Surgeon-Major Macnamara suggested to Messrs Arnold and Sons a modified form of grip forceps which upon trial have been found to answer extremely well. The extracting forceps overcome many difficulties hitherto presented. The form of grip represented in the engraving grasps firmly and holds a bullet securely in whatever position it may be caught. The bullet cannot rotate or slip when the forceps are closed upon it. Another important feature is that the end of the improved forceps is perfectly smooth and forms a probe, in fact, the instrument is a bullet probe and extractor combined. It further possesses the advantage that it is not liable to tear or injure the tissues. This particular grip will, it is believed, extract not only the new bullet, but will be found useful in the removal of bullets of any shape. Foreign substances also of whatever nature, can be grasped and removed by its intervention.

VOYAGES FOR HEALTH'S SAKE

To the Editors of THE LANCET

SIRS,—I wish from this side of the world to enter a protest against the indiscriminate shipping to these colonies of invalids, more especially those who are suffering from phthisis. Each year, about October, certain sailing ships which have the name of being "invalid ships" leave England for Australia, arriving here in our very hottest months—January or February—when the temperature in the shade is often 104° or 105° F. The trip generally takes from ninety to 100 days, out of these about half are in warm climates. If practitioners at home would consider that their patients would be shut up in stuffy cabins and saloons, with ports sometimes closed for days together, surrounded by fellow passengers in all stages of phthisis in an atmosphere which must necessarily reek with the bacilli of tubercle, and give heed to other circumstances I am sure they would think twice before recommending such a trip. Each year patients come out who have left home with only slight mischief, but who on arriving here are in the last stages of phthisis, having slept probably in the same cabin with a patient who may have been far advanced with phthisis on leaving home, and they have to die out here away from friends and home comforts. Only a few days ago I saw a young fellow who had left home with slight physical signs at one apex, who, on arriving here, was simply dying of general tuberculosis. On recommending him to return by the fastest mail boat the following day he went back to his hotel and committed suicide by shooting himself being so depressed at the idea of another voyage. The best voyage to take for health's sake, I should say would be by a steamer coming round the Cape of Good Hope, with plenty of cabin space, good food and a thoroughly qualified medical officer on board.—I am, Sirs, yours truly,

R. HUMPHREY MARTIN M.B. Cantab, M.R.C.S.
Adelaide, South Australia, February 12th, 1893.

fibrins, coagulated proteids, albumoses and peptones, and lardacein or amyloid substance. Next the enzymes are considered, including ptyalin, amylpsin, pepsin, trypsin, pialyn or steapsin, rennin, fibrin ferment, muscle enzyme and urea ferment, and then the nitrogenous non crystalline bodies allied to proteids, such as mucin, gelatin, chondrin, elastin, keratin, neurokeratin, chitin and nuclein. Then follow the carbohydrate, the fatty acids and the fats with their allies. The amides and amido acids come next, with urea and the uric acid group and the aromatic series. A short section is devoted to the ptomaines, and the remaining pages are occupied with an account of the colouring matters of the blood, bile and urine. In many instances—as, for example, in glycine, sarkosine, taurine and kreatin, and in the alloxan and allantoin series—the graphic as well as the molecular formulæ are given, which is of advantage, since it enables the industrious student to comprehend the process of the derivation of these complex substances from the more simple compounds and to understand their chemical relations, providing only that he has been already well grounded in the chemical laboratory.

It is difficult to select any particular section, where all are good, to show the mode in which Mr. Lea treats his subject, but we may take the glycolic acid series as an example. "Lactic (hydroxy propionic) acid ($C_3H_5O_3$). Thus, after carbonic acid, is to the physiologist the most important acid of the series. If lactic acid be regarded as derived from propionic acid (CH_3CH_2COOH), it may be noticed at once that two isomeric lactic acids must be capable of being formed from it. These acids will have the following formulæ respectively $CH_3CH(OH)COOH$ and $CH_3(OH)CH_2COOH$. Of these the first is known as ethylidene lactic acid, the second as hydracrylic acid. In addition to the above, a third acid—isomeric with ethylidene-lactic acid—is known, namely, sarcocollactic or paralactic acid. Of these three acids only two occur in the body, hydracrylic acid being absent. A fourth acid, to which the name of ethylene lactic acid has been given, has also been described as isomeric with hydracrylic acid. It is, however, probable that this acid is really acetyl lactic acid, hydracrylic acid being the true ethylene lactic acid."

The several forms of lactic acid are then described with their chief salts, and illustrations are given of their crystals. Mr. Lea by no means restricts himself to the substances actually found in the animal body, but gives interesting sections on various compounds that have a biological interest. As an example which will show well his method of dealing with such substances, his account of asparagin may be selected. The composition of asparagin he gives as $C_4H_8N_2O_3 + H_2O$, or $COOH \cdot CH_2 \cdot OH(NH_2) \cdot CONH_2$, amido succinamic acid, and he goes on to observe that, although asparagin is not found as a constituent of the animal body, it is a substance of considerable interest to the physiologist, for not only is it closely related to aspartic acid, into which it may be converted by the action of boiling acids and alkalies, yielding at the same time ammonia, but it undoubtedly plays a most important part in the constructive proteid metabolism of plants. Further, it exists in not inconsiderable amount in many plant tissues used as food by man, and is known, like so many of the members of the numerous class of amido-acids to which it belongs (leucine, glycine &c.), to give rise to urea when taken into the bodies of carnivora and to uric acid in those of birds. "In plants asparagin, like leucine, is found chiefly in those parts which afford a store of reserve material, such as bulbs, tubers &c., and the cotyledons of seeds. The amount is, however, largely increased during germination, and it is therefore frequently present in very large quantities in seedlings—as, for instance, in those of yellow lupins. The increase in the young growing plant is most probably due chiefly to a formation of asparagin out of the decomposition of reserve proteids, although some may be formed synthetically. The amount is greatest when the seeds are germinated

in the dark, and the seedlings subsequently grown for time in semi obscurity and shielded from the access of carbonic anhydride. Under these conditions the formation of non nitrogenous [? carbohydrate] material is simultaneously prevented, and, putting the two facts together it appears probable that the disappearance of asparagin in seedlings grown under ordinary conditions is due to its consumption for the synthetic production of proteids. The chemical characters of asparagin are then given by the author, and he proceeds to say "One point of interest with respect to asparagin remains to be briefly mentioned. Seeing that in plants the nitrogen requisite for the construction of proteids appears to be obtained largely from asparagin, is there any evidence that in animals also the nitrogen of this substance can take the place of that of proteids? The answer to this question may be stated as follows. When asparagin is administered to carnivora or birds, practically the whole of it is converted into urea or uric acid. Thus in carnivora at least there is no diminution of proteid metabolism, such as is observed under a gelatin diet when asparagin is added to the food. In herbivora, on the other hand, there appears to be somewhat distinct evidence that a part of the nitrogen in proteids may be replaced by that of asparagin." This is all extremely well put and is highly suggestive, and in a final paragraph Mr. Lea remarks that the question as to the importance of the nitrogen of asparagin as a possible replacer of that of proteids arose first in connexion with the dispute, referred to in a previous page, on the mode of formation of fats in the animal body. In certain experiments employed by Voit as a basis for his views a diet of potatoes was largely used. The amount of nitrogen in these was calculated from the total nitrogen they contained, on the assumption that there was no nitrogen present in them in any form other than that of proteids, but potatoes contain much asparagin, so that, making allowance for this, the total amount of proteid given in the experiments alluded to was much less than was supposed, and might not have sufficed to account for the fat stored up. "This difficulty," Mr. Lea observes, "would obviously be got over if it could be shown that the nitrogen of asparagin can play the part of the nitrogen of proteids."

The account of the colouring matters of the animal body is very complete. It includes those of the blood, hæmoglobin and its derivatives, with the combinations of that substance with carbon monoxide, nitric oxide and carbon dioxide, methæmoglobin, hæmocyanin, hæmochromogen, hæmatin, histohæmatin, hæmin, hæmatoporphyrin and hæmatoidin.

The perusal of the work leads to the conclusion that, though slowly, yet still surely, we are acquiring a more thorough knowledge of the organic compounds found in, or capable of being extracted from, the body. This is seen in such examples as the enzymes and their action on different substances, the peptones and their several forms, and the pigments of the blood, bile and urine, to which we have already referred. The work may be accepted as an authoritative exposition of the present state of our knowledge of the chief constituents of the body, and is a valuable appendix to Foster's Physiology.

LIBRARY TABLE

Burdett's Hospital Annual and Year book of Philanthropy for 1893. Edited by HENRY C. BURDETT. London: The Scientific Press.—No one who takes up this book and examines even cursorily its contents can fail to be impressed with its value, especially to those who are engaged more or less directly with hospital work in its various departments. A rapid glance at the index will show the wide extent of the information it conveys in respect of the institutions of a medical and philanthropic kind distributed throughout the three kingdoms. Its pages present an *embarras de richesses* almost provoking by its very voluminousness. And yet such

the latest exposition of the bearing of his researches on the great problems of life and organisation and of his being admitted into its membership. We are more concerned to-day to notice the significance of the general reception which Professor VIRCHOW has received in this country, and especially by the profession at large, as represented by the banquet on the evening of the 16th inst. The address to the Royal Society will remain an achievement of scientific exposition in the happiest English by a distinguished foreigner, and it is the less likely to be forgotten on account of its generous recognition of the work of English physicians and physiologists HARVEY and GLISSON and HUNTER and BROWN, and the host of workers whom they represent, will live more vividly in the history of physiology and of medicine for the tribute, minute and justified, of the Croonian Lecturer of the Royal Society for the year 1893. Not the least interesting to medical practitioners, though perhaps a little less expected, was the part of Professor VIRCHOW's tribute which alluded to the personality and the work of BROWN—to what he called "the new system of medicine founded in Scotland," of which in later years, under the auspices of Dr TODD we have had a resuscitation in England. The division of diseases into sthenic and asthenic, according to the apparent amount of vital force in them, has ever since BROWN's time been a feature in the estimate of disease not by the people only but by medical practitioners. No theory has had more to do in dominating practice—sometimes in wrong directions, at other times in right directions, but in very wrong degrees. But this like many other parts of the Croonian Lecture, is matter for separate notice and is not the special object of our present article.

We are concerned now with the interest of the episode of Professor VIRCHOW's visit as a whole and as an event in the history of the profession. The eloquence of the evening gathering was not unworthy of the occasion. It represented all that was best in the Royal Society, and all that was best in the medical profession besides being an illustration of the close connexion of medicine with science in its deepest parts and with the great society which has always cultivated close relations with the faithful workers in medical science. The speech of Lord KELVIN at the dinner clearly showed his recognition of the advance made by Professor VIRCHOW and the students of the cell in physiology and pathology. There was a little touch of humour indeed, in the way in which he indicated the fact that, in localising the secrets of life in the cell instead of in the egg, as HARVEY did, we are not much nearer the discovery of the nature of this essential and mysterious principle. This much, indeed, was practically admitted throughout by the Croonian Lecturer himself and by all the speakers at the banquet. The advocates of spontaneous generation were conspicuous by their silence if not by their absence, and for the time being, at any rate, in this gathering of the foremost men in the sciences—like of physics and of biology—there was the frankest recognition of the continuity of life from life—of cell from cell—leaving to future ages the solution of the problem of the origin of first life and the discovery of the nature of all life. Mr HUXLEY, whose title (as a member of the Privy Council) of "the Right Honourable" seemed to puzzle the toastmaster is not only famous as an anatomist and biologist, but has claims to be regarded as a perfect

type of the scientific speaker. His presence at what was essentially a gathering of the medical profession was a pleasing compliment not only to the host of the evening, but to the profession of which, like most anatomists and biologists, he is an honoured member. His speech was in admirable taste and gave his audience, as did also the speech of Sir JAMES PAGET, a wonderful idea of the range of Professor VIRCHOW's work. Not the least advantage that should accrue from the visit of our distinguished guest is the indirect proof which his account of English work in physiology and medicine affords of the value of the study of life as distinguished from that of death of the study of living animals as distinguished from mere morbid anatomy. The turning point of medical science—at which it made a start on the road which is now conducting it to the greatest discoveries—was when HARVEY began to set the example of studying organs in action as well as dead parts. "Here for the first time," says Professor VIRCHOW, "the anatomical examination of living parts was carried through in an exemplary way, according to experimental methods." This is the high praise to an Englishman which a foreigner has to offer in a country where he finds such workers hindered by a suspicious and ungenerous law. We believe that the nation, which really regards its medical profession with respect, will see that if the glory of yet greater discoveries is to be achieved by Great Britain the restrictive legislation to which we refer will have to be relaxed. Finally we must again express our sense of the pleasure which the visit of our eminent German colleague and the ovation he has received alike in London and at our principal seats of learning has afforded us. Such international hospitalities should be multiplied. They do immense good to the profession at home and stimulate it to further efforts, they bring before the public mind the true greatness of medical science and they enhance the friendliness of nations and of their true leaders.

Few symptoms may arise from a greater variety of causes than uterine hæmorrhage, and whilst sometimes it may be of comparatively small importance, at others it may have the gravest significance. It should therefore never be disregarded or treated lightly till the reason for it has been satisfactorily ascertained or, at all events, till every effort has been made to determine its cause. It may be said that these are merely general principles such as are acted upon by every earnest practitioner in every department of medicine—that, in fact, this is merely another way of saying that diagnosis should precede treatment, and this is true up to a certain point. For instance, to take as an example a common symptom, such as diarrhoea, it is obvious that all practitioners having excluded the more serious diseases likely to cause the condition, must at times be content to prescribe for it without always being able to say positively to what it may be due. We have not taken this symptom by any means at random. Indeed, within our knowledge a case occurred even in hospital practice in which a patient was treated for simple diarrhoea for twelve months by various astringent mixtures without benefit. At last, when a local examination was made, a large gall stone was found partially embedded in the recto-vaginal septum. In this instance the fact

THE LANCET.

LONDON SATURDAY, MARCH 25, 1893

IT is natural that the annual meeting of the Fellows of the Royal College of Physicians of London, held on the day after Palm Sunday, should excite an interest in the profession far beyond the limited circle immediately concerned in the proceedings. For on this day the Fellows assemble to receive from their President his account of the duties that have fallen to him during his year of office, together with his sketches of the lives of those Fellows who have ended their earthly career since the last anniversary, then the Comitia proceed to elect a new President, and it is upon their choice that much may depend in regard not only to the position of the College, but also to the general status of the profession in this country. In some respects the College occupies a unique position and exerts an influence for good far beyond any claims which may be made on its standing as an historical institution. For, notwithstanding the criticism of those who think its government should not be limited to the Fellows who form the minority of the body corporate, in spite, too, of the ungenerous taunts of others who would fain deprive it of its long established rights, there is no gainsaying the fact that this College has exerted and does continually exert a most wholesome influence on the profession of medicine in this country. The bestowal of its Fellowship means something more than recognition of professional ability or of success in practice, and it is not surprising that its possession is valued and sought after, for it is known that every care is taken to make the selection impartial and just. In spite of all that may be said of the action taken by the College in questions of ethics, which from time to time are brought under notice—questions admitting often of great differences of opinion—it must, nevertheless, be freely recognised that its judgments have been such as reflect the best traditions of an institution which, in these difficult and delicate matters, has to act the part of the conscience of the medical body corporate. The College has always been a jealous guardian of professional honour. It has, especially of late years, taken also a most prominent—nay, a leading part in medical education. It is regarded also by the State as the chief representative body of our profession, and has often been appealed to on questions pertaining to the public service.

The position of President of such an institution must therefore be one of great responsibility as well as of high honour. He has behind him a long roll of names of physicians chosen for this office, on various grounds, it may be, but mainly by reason of their personal worth and the feeling that they are capable of setting the standard of right in professional conduct for their brethren to attain unto. To the general public he is the embodiment of the ideal physician, to the profession he is the arbiter of questions of disputed ethics, whilst to his own College he has to devote himself with an assiduity which can only be shown at much self sacrifice. The office of President of the College

of Physicians nowadays is no sinecure. The multifarious matters which come under its purview must demand of him a large amount of practical acumen and a sound judgment if the College is to maintain the position it has so long held. This being so, it is obviously to the advantage of the College, and therefore of the profession at large, to retain in office the same physician who has held the chair for several years—one who is well acquainted with its duties, and has taken a leading part in all the developments of its work. But the College could only do this if the President himself were wishful to retain a position fraught with so much personal inconvenience. We believe that we are only expressing a general feeling when we state that the continuance of Sir ANDREW CLARK in office for at least another year will be very welcome to the profession at large. He completes on Monday a term of office which has only been exceeded by his much respected immediate predecessor since the time of Sir H. HALFORD's lengthy reign. As a general rule, it may not be desirable to re-elect a President for a longer term than five years. It is hardly fair to him to demand so great a tax upon his endurance, moreover, repeated re-elections afford less opportunity for a trial of administrative talent which may be latent in the Comitia of the College. It seems to us, however, that the Fellows would act wisely and consult the best interests of the College and of medical education by once more calling Sir ANDREW CLARK to office. That he has claims to such a recognition of his untiring exertions, his ripe judgment and his frank generosity must be admitted, and unless he himself would desire retirement from so arduous a post there ought to be no hesitation in re-electing him, particularly as the still burning question of a University for London, in which he has shown so keen an interest, is still unsettled.

Believing that this will be the decision taken on Monday, it is hardly worth while to discuss other eventualities. Many an honoured name occurs to us which we would fain see enrolled on the presidential list, but which, for reasons concerned mainly with the all engrossing duties of the office, it would be no kindness to propose. There is, however, one name which has often been prominently brought forward—that of a physician whose long activity in matters concerning education and medical legislation has marked him out as well entitled to the honourable position to which he has attained in the General Medical Council. It would, however, be singular if Sir RICHARD QUAIN should be called to fill both these positions at the same time, and certain recent litigation emphasises the incongruity of one individual presiding over two bodies having functions of such a different scope. Indeed, as far as he himself is concerned, we understand that in view of the important work in which the present President is personally engaged on behalf of the interests of the College as affected by the proposed teaching University in London, Sir RICHARD QUAIN does not wish to stand in the way of Sir ANDREW CLARK's re-election on the present occasion.

THURSDAY, March 16th, is a day to be remembered in the annals both of the Royal Society and of the profession of medicine. We have already observed on the seemliness of this society hearing from the author of cellular pathology

not only be profoundly disappointing to all believers in human progress, but it would tend to paralyse all effort put forth for the betterment of the degraded and criminal classes. It is very satisfactory to find that Sir EDMUND DU CANE, with his large official experience and his association with those most likely to possess trustworthy information on the subject, is decidedly of opinion that crime is undergoing a sensible and progressive decrease.

First, as to the returns of the prison population since 1877. These indicate not only a decrease, but, what is much more important, a practically continuous annual decrease. The average number in local prisons in 1878-77 was 20,361, while in 1891-92 it was 12,663. In 1869 there were 2006 sentences of penal servitude, in 1891 the number was 751. Here we have a notable and most satisfactory decrease. In reply to those who allege that this decrease can be explained by a shortening of sentences, Sir EDMUND DU CANE says that, even if this shortening of sentences be a factor in the case, yet "there is no evidence of the consensus of such a large number of independent sentencing courts as would justify the assertion as a general rule", further, that a shortening of sentences "would not account for the continuance of the fall year after year, for the sentences have certainly not been proportionately shortened year after year." Equally inadequate, in the writer's view, is the suggestion that this decrease may be explained as due to the general substitution of fining for imprisonment.

Again, a great fallacy would seem to lurk in the argument of those who regard the increase in the number of juveniles in reformatories and industrial schools as an evidence of an increase of crime. In point of fact, these institutions are of comparatively recent growth, their great development dating from the Reformatory and Industrial Schools Acts of 1866. Further, the returns from these two classes of institution are fallacious if considered *en bloc*. The reformatories are "penal and reformatory institutions for young persons convicted of crime and correspond therefore to prisons. The industrial schools, on the other hand, are preventive institutions for children who have not been convicted, but might fall into crime for want of proper care and training." It is clear, therefore, that an increased number of juveniles in the industrial schools would point simply to greater activity on the part of the authorities as regards preventive measures and would throw no light on the problem before us.

Further evidence is afforded by the annual police returns regarding the number of what are known to them as the criminal classes. Since 1867-68 the decrease in the number of these classes has been practically continuous and has fallen from 87,663 to 51,095. As to crime, the police returns point to a not less satisfactory decrease. The Commissioner of Police of the Metropolis in a recent report shows that the felonies in 1830 were fewer by 2053 than in 1889, and points out that the felonies are now less than half the number considered normal twenty years ago. The Chief Constable of Liverpool reports that the number of indictable offences committed during the year ending Sept. 29th, 1891, was 907 less than during the year ending Sept. 29th, 1890, and 967 less than the year previous to that, whilst minor offences of violence had fallen from 1952 to 1546. Mr GROSVEEN of the Home Office, in a paper read before the Statistical Society in 1890, summed up his conclusions by saying "It is obvious that

these combined causes have materially assisted in securing the abatement shown to have taken place in nearly all classes of crime during the last twenty years, whilst the great reduction in the number of known thieves and other suspected persons at large, as well as in the houses of bad character which they frequent, and more especially the extraordinary diminution in the number of receivers of stolen goods, has made manifest the increasing efficiency of the police. When to this is added the fact that during the period in question the population of England and Wales has increased by nearly six millions and a half, we must admit that the many agencies enlisted for the purpose of diminishing the number of criminals have been most successfully applied, and the result cannot fail to afford the utmost satisfaction and encouragement to all who are anxious for the improved moral and physical advancement of our nation."

These conclusions afford a solid basis for a hopeful prognosis regarding the future of crime. It would be contrary to all the probabilities of the case that education, philanthropy, legislation, the wider diffusion of material comfort, and the general spread of refining and humanising influences should fail to produce any diminution in the prevalence of crime. We are told by the pessimists that education only gives us more adroit criminals and that increase of wealth only multiplies the temptations to fraud and violence. We decline to accept so disheartening a view as this, and we are thankful to Sir EDMUND DU CANE for strengthening our belief in the moral progress of humanity.

Annotations.

"No quid nimis."

THE INTERNATIONAL MEDICAL CONGRESS

AN Italian correspondent writes under date, Rome, March 19th—"Only six months now divide us from the opening of the Congress and still the work of preparation proceeds with alacrity. To the lists already given of important provincial committees organised to coöperate with the central committee in promoting the solidarity of the Italian representation I have now to add that of Milan, over which Dr Giovanni Rosmini has been elected to preside, the vice-president being Dr Francesco Denti and the secretaries Drs Pietro Ramazzotti, Torquato Sironi and Giuseppe Pessina. The 'Esposizione,' which is to constitute so useful and impressive a feature of the Congress has also an organising delegate from the Milanese province in Dr Vincenti, well known in every department of practical sanitation. The circular issued by the committee at Milan justly remarks that the profession, not only in the towns, but in the country parishes, includes practitioners of approved knowledge, sagacity and experience, whose presence at the Congress is on every ground desirable, and to these it addresses an urgent invitation to seize the opportunity of exchanging views with their brethren not less thoroughly equipped from other parts of the peninsula. In this way the *fratellanza* between all branches and representatives of the healing art in Italy is furthered, as a preparation for that larger *fratellanza* (or brotherhood) which unites practitioners of all nationalities in the same grand cause of medical science and endeavour. Meanwhile the correspondence between the central committee and the profession in non-Italian countries has fructified satisfactorily. This has been conducted mainly

that treatment had preceded diagnosis had not done the patient any great harm, but there are special circumstances, unfortunately, in the case of metrorrhagia which not infrequently lead to the most lamentable consequences to the patient unless accurate diagnosis be made the first consideration. For instance, there is the knowledge on the part of the medical attendant that many patients are exceedingly unwilling to submit to examination, and therefore a natural disinclination on his part to urge upon them a course that would certainly be unpleasant, and might afterwards prove to have been unnecessary. Then, again, there may sometimes be a doubt in the practitioner's mind whether, after obtaining the patient's consent, the result of the examination would be as conclusive as could be wished. For these reasons the practitioner may be inclined to think there can be no harm in waiting for a little time, and trying the effect of the various medicines reputed to be useful in the treatment of metrorrhagia before determining upon a thorough investigation of the case. Yet it is scarcely possible to insist too strongly on the fact that a certain proportion of women who suffer from losses of blood, or a blood stained discharge between the menstrual periods are suffering from cancer of the uterus, and the responsibility rests with those in attendance to make sure, as far as possible, that a case with this symptom is not a case of cancer before proceeding to treat it by simple remedies such as ergot or hamamelis. If this be borne in mind a larger proportion of cases than at present would be seen in time for operative treatment to have a fair chance of success. There are some popular fallacies, as our readers are well aware, prevailing amongst women themselves with regard to this subject. For instance, there is the notion that pain is invariably associated with cancer, and that consequently so long as there is no pain they may safely assume that their ailment, whatever it may be, is not, at all events, cancer. Similarly, even a larger class of patients erroneously fancy they must be the victims of cancer because they suffer pain. The fact of course is that, as regards cancer of the cervix, pain does not generally occur till a late period in the case, when the disease has reached an advanced stage and satisfactory treatment by operation has become impossible. It is true that in cases of primary cancer of the body of the uterus pain is often an early symptom, but, as is well known, in by far the largest number of such cases the disease begins in the cervix, and here what has been said above applies. Another erroneous prevailing impression is that the disease is necessarily one of advanced life. Now, whilst this is so as regards primary cancer of the body of the uterus, it is certainly not so as regards the cervix. We not rarely meet with cases of the latter class between the ages of twenty five and thirty, and after thirty they become comparatively common. Again, we must not lose sight of the fact that there is not infrequently some misapprehension as to there necessarily being an offensive discharge in cases of cancer. Such a discharge is practically always present sooner or later, but it is usually later, the point to be remembered is that in many early cases of cancer of the uterus the discharge is not at all offensive. This applies to both classes of cases. The absence of an offensive discharge must not for a moment be taken as warranting a conclusion that the patient is not suffering from cancer.

On the other hand, whilst there is almost always an offensive discharge at some period or other in cases of cancer, an offensive discharge does not of course by itself warrant a diagnosis of cancer.

All whose practice deals more especially with the diseases peculiar to women have doubtless seen cases of advanced uterine cancer where valuable time has been lost in unavailing treatment by internal remedies and the use of some simple vaginal douche. In some of these cases perhaps no examination whatever may have been made. Great advances, however, have been made of late years in the diagnosis of cancer, and so far as the profession itself is concerned there is a more general recognition of the significance of intermenstrual hæmorrhages. Now, whilst any intermenstrual hæmorrhage should excite a suspicion that there may be something seriously amiss, and lead to a thorough investigation, it is not too much to say that hæmorrhage after the menopause is generally due to cancer. There are, of course, exceptions to this as to most other rules, but the safest plan is to regard any case of hæmorrhage after the menopause as possibly due to cancer till an examination has been made. Even if no evidence of anything abnormal is discovered by an ordinary vaginal examination, it should not be forgotten that the disease may be beginning in the supra vaginal cervix, or even in the body of the uterus, and certainly the persistence of a sanious discharge should lead to a further investigation—that is to say, the cervix should be dilated, so that the condition of the supra vaginal cervix, and of the interior of the body of the uterus, may be ascertained.

It would seem at first sight a comparatively simple matter to determine whether in a given country and for a given period crime has increased or decreased, but the problem is not so simple as it looks and experts are found to differ in their conclusions. Difficulties arise from different classifications of crime, from varying lengths of sentences according to the special views of those concerned in the administration of justice or the altered temper of the times, from a change in public sentiment regarding such matters as capital punishment and transportation, from different methods in dealing with juvenile offenders and from fluctuations in preventive legislation. These are only a few of the factors which introduce doubt and difficulty into the correct appraisement of criminal statistics, and we must not be surprised if this department of sociology presents some of the perplexities which more or less beset all sociological problems. An attitude, however, of suspended judgment on such a broad question as whether in this country crime is tending to increase or decrease cannot be very long maintained, and whilst allowing full weight for the special difficulties of the case we naturally crave for some assurance that all the legislative, educational and philanthropic effort in which the century has been so rich is bearing fruit. Hence Sir EDWARD DU CAVE's article in the current number of the *Nineteenth Century* will be rather a relief to many of his readers. He writes avowedly to controvert the gloomy views of some recent authorities who have sought to show that the improvement in criminal statistics is apparent rather than real, and that there is no satisfactory evidence that advancing civilisation and the spread of education tend to make men morally better. A conclusion like this would

not only be profoundly disappointing to all believers in human progress, but it would tend to paralyse all effort put forth for the betterment of the degraded and criminal classes. It is very satisfactory to find that Sir EDMUND DU CANE, with his large official experience and his association with those most likely to possess trustworthy information on the subject, is decidedly of opinion that crime is undergoing a sensible and progressive decrease.

First, as to the returns of the prison population since 1877. These indicate not only a decrease, but, what is much more important, a practically continuous annual decrease. The average number in local prisons in 1876-77 was 20,361, while in 1891-92 it was 12,663. In 1869 there were 2006 sentences of penal servitude, in 1891 the number was 751. Here we have a notable and most satisfactory decrease. In reply to those who allege that this decrease can be explained by a shortening of sentences, Sir EDMUND DU CANE says that, even if this shortening of sentences be a factor in the case, yet "there is no evidence of the consensus of such a large number of independent sentencing courts as would justify the assertion as a general rule", further, that a shortening of sentences "would not account for the continuance of the fall year after year for the sentences have certainly not been proportionately shortened year after year." Equally inadequate, in the writer's view, is the suggestion that this decrease may be explained as due to the general substitution of fining for imprisonment.

Again, a great fallacy would seem to lurk in the argument of those who regard the increase in the number of juveniles in reformatories and industrial schools as an evidence of an increase of crime. In point of fact, these institutions are of comparatively recent growth, their great development dating from the Reformatory and Industrial Schools Acts of 1866. Further, the returns from these two classes of institution are fallacious if considered *en bloc*. The reformatories are "penal and reformatory institutions for young persons convicted of crime and correspond therefore to prisons. THE INTERNATIONAL MEDICAL CONGRESS

AN Italian correspondent writes under date, Rome, March 19th—"Only six months now divide us from the opening of the Congress and still the work of preparation proceeds with alacrity. To the lists already given of important provincial committees organised to coöperate with the central committee in promoting the solidarity of the Italian representation I have now to add that of Milan, over which Dr. Giovanni Rosmini has been elected to preside, the vice-president being Dr. Francesco Denti, and the secretaries Drs. Pietro Ramazzotti, Torquato Sironi and Giuseppe Pessina. The 'Esposizione,' which is to constitute so useful and impressive a feature of the Congress, has also an organising delegate from the Milanese province in Dr. Vincenti, well known in every department of practical sanitation. The circular issued by the committee at Milan justly remarks that the profession, not only in the towns, but in the country parishes, includes practitioners of approved knowledge, sagacity and experience, whose presence at the Congress is on every ground desirable and to these it addresses an urgent invitation to seize the opportunity of exchanging views with their brethren not less thoroughly equipped from other parts of the peninsula. In this way the *fratellanza* between all branches and representatives of the healing art in Italy is furthered, as a preparation for that larger '*fratellanza*' (or brotherhood) which unites practitioners of all nationalities in the same grand cause of medical science and endeavour. Meanwhile the correspondence between the central committee and the profession in non-Italian countries has fructified satisfactorily. This has been conducted mainly

through the presidents of the nineteen sections into which the work of the Congress has been distributed, and the result has been that, partly through direct appeal and partly through intermediate negotiation, men of light and leading in the various subjects these sections cover, have promised, or have actually sent in, contributions bearing on the topics prescribed. Within the last few days, in fact, communications in this sense have been received from Great Britain, France, Spain, Germany, Switzerland, Austria Hungary, Belgium, Holland, Denmark, Sweden and Norway, Russia, Turkey, Egypt, the United States and Australasia. A representative of the Congress, when passing through Calcutta, had an audience of the Viceroy, and, at the request of the Indian Government, the central committee has instituted in the Section of Hygiene a subsection to deal with Asiatic cholera, its etiology, its mode of propagation, its prevention and its treatment. The Surgeon General (Dr W. R. Rice) has, I understand, deputed Dr Cunningham to represent Indian medicine at the Congress. The French Minister of Marine will also send a delegate in the person of the medical officer in chief of the navy, Dr Rouvier, member of the superior council of the sanitary service of the fleet. The Peruvian Government has, further, notified the central committee that its deputy at the Congress will be Dr Aurelio Alarco, one of the most distinguished consultants in the school at Lima, whilst the Governments of Paraguay, Colombia and Ecuador have responded to the invitation of the central committee by an undertaking to nominate their representatives *quam primum*. At the Policlinico itself—the seat of the Congress outside the Porta Pia and near the British Embassy—the Palazzo dell'Amministrazione, in which the sittings will be held, is progressing rapidly towards completion. The magnificent cornice of the palace—a *chef d'œuvre* of the Society of the Stuccatori (artists in stucco ornamentation)—has, thanks to the dry, sunny weather, been brought to a close in a wonderfully short time, the work employing as many as forty hands a day. This part of the building, indeed, will rank as one of the best artistic productions of modern Rome, worthy of the institution it ornaments and of the Congress which will be the first to witness it."

THE SHOP HOURS BILL

WHATEVER may be the ultimate fate of the measure introduced by Sir John Lubbock for the reduction of hours of labour in shops, it is evident that public opinion as a whole is convinced of its utility and of its moderation. Twelve, fourteen and sixteen hours a day are terms which under any rational system of trade would much more than satisfy all commercial exigencies. Their duration bears no true proportion to the work in hand. It is merely the outcome and expression of an unregulated struggle for existence amongst traders, in which the public health and every other interest is subordinated to the ambition or the supposed necessities of the individual. Its ruinous influence upon the health of the employed calls for no fresh assertion on our part. This has been proved beyond question in the experience of every medical practitioner whose calling brings him into contact with the class in question. Clergymen and others have protested against its demoralising tendency, for obviously the unfortunate whose every waking hour on every day save one in the week is practically spent in a routine of work or business worry can hardly be capable in any remaining fraction of leisure, even if he has the opportunity, of endeavouring after mental or moral self-improvement. Life in his case becomes, but for the mental slavery, we will not say activity, involved in his business duties, little better than a mere process of physical effort alternated with hurried attention to bodily necessities and appetites. It is therefore not to be wondered at that we find trade councils,

factory inspectors, shopkeepers themselves and shop assistants all over the country, though uncombined by any plan of alliance, yet agreed in a general dissent from this established disorder of things. The new Bill is but the voice of the dissentient spirit. It is, therefore, no forced or artificial measure. All that it seeks to do is to assert the right of a preponderating majority to control in an essential matter of trade custom the hostile independence of a small and selfish minority. Its results can be guaranteed as beneficial, its method is regular and constitutional, and its ultimate success must therefore be only a matter of time. It already possesses, in the support of members on both sides of the House of Commons, an earnest of acceptance by the Legislature which we hope will not wait long for its needful confirmation.

BLACK TONGUE

THE condition in which the dorsum of the tongue is more or less covered by a black patch is not very uncommon, but its etiology is somewhat obscure. It has been called "hyperkeratosis" with the idea that the superficial layer of epithelium becomes hypertrophied, undergoing horny degeneration, with atrophy of some of the cells and a development of black pigment. Drs Ciaglinski and Hewelke, writing in the *Kronika Lekarska*, describe a case in which they were able to find a mould in the black patch somewhat resembling mucor rhizopodiformis, which contained black pigment. The case was that of a woman who a fortnight previously had had some kind of feverish attack—most probably influenza. The tongue looked as if it had been covered with blacking the discolouration extending as far back as the circumvallate papillae. By means of borax washes the tongue became clean in a couple of days. Examination showed a black mould which could be well cultivated on bread or on potatoes at the temperature of the room, but which did not grow at 37° C. It was apparently of a harmless character, for it was injected into the veins of rabbits without effect. Drs Ciaglinski and Hewelke distinguish two kinds of black tongue—the chronic, due to anatomical changes in the epithelial layer, and the acute, which depends upon the presence of a mould. This is harmless apparently to internal organs, as it does not develop at the temperature of the body.

POPLAR AND STEPNEY SICK ASYLUM RETIREMENT OF, AND TESTIMONIAL TO, DR GOLDIE

EXTENSIVE alterations are in progress at the Poplar and Stepney Sick Asylum, Bromley. The present building was erected under Gathorne Hardy's Act, which enabled unions to combine together for the purpose of treating their sick poor. It was constructed on the pavilion system, and was opened for the reception of patients on Aug 7th, 1871. It accommodated 586 patients, but the pressure on the institution has been so great during the last ten years that Dr R. W. Goldie, the medical superintendent, found it necessary to recommend the managers to add three beds to each ward, bringing the total number of beds up to 640. The beds are divided nearly equally between the two sexes. This temporary measure having proved insufficient the managers decided upon erecting two new pavilions at the east end of the institution, where there was a large vacant space used as a recreation ground. The new blocks will accommodate about 200 patients. It is expected that this much needed extension will be ready for the reception of cases in about twelve months. At the west end of the building a large nursing home is being erected. It will include a large recreation hall and provide rooms for from forty to fifty nurses. After a service of twenty-two years at the hospital, Dr Goldie has resigned his appointment on account of ill health and has been succeeded by Mr W. H. Pearce, formerly house surgeon at the Sheffield.

Hospital and for the last ten and a half years assistant medical officer in the asylum. Before his appointment as the first medical superintendent to the Poplar and Stepney Sick Asylum Dr Goldie served for three years in a similar capacity at Chorlton Union Hospital, the first hospital in the Poor law service built upon the pavilion plan. His term of office has been signalled by very considerable activity both in surgical practice and in administrative work, and the asylum is indebted to him for many improvements and additions to the comfort of the inmates. The chief operations performed at the hospital have been lithotomy, hepatotomy, excision of the tongue, lower jaw, head of the humerus, elbow joint and wrist-joint, and about thirty amputations, including Syme's and Pirogoff's amputations, amputation through the knee-joint and at the seat of election and several through the lower third of the thigh. Virtually, there has been no death rate, a fact which speaks volumes for the skill of the surgeon and the admirable sanitary arrangements of the hospital. Dr Goldie retired formally from office on Saturday last, the 18th inst., and the general staff of the hospital embraced the opportunity to present him with a testimonial as a mark of appreciation of his services to the institution, his care for the welfare of the patients and his attention to the interests of the whole of the working staff of the hospital. There were no less than eighty-seven subscribers. The testimonial comprised a dessert service, a silver tankard, a pair of opera glasses and an illuminated address. Complimentary speeches were made by Mr Pearce (the visiting clergyman), Mr Foskett (clerk to the board) and Mr Rivington, who, though not formally appointed to the office of consulting surgeon to the institution has been called upon with the approval of the board to give his opinion in important surgical cases during the greater part of Dr Goldie's tenure of office, and has been present at a large majority of the operations performed at the asylum. We may add that some years ago Dr Goldie was offered by Mr Stansfeld an inspectorship under the Local Government Board in recognition of his services, but declined it. It is to be hoped that after a short rest his health will be re-established and that he will find a new sphere for the exercise of his undoubted professional and administrative abilities.

ACCIDENTS IN INGUINAL COLOTOMY

IN a short paper on a year's work at his clinic for Diseases of the Rectum, published in the *New York Medical Journal* of Feb 18th, 1893 Dr C B Kelsey mentions two cases of inguinal colotomy in which a noteworthy accident occurred. In one case, twenty-four hours after the operation a remarkable flow of serum, which completely soaked the dressing was observed, and when the dressing was removed three or four feet of gut were found to have escaped from the wound, and to be "strangled and cold." The wound was opened up the prolapsed bowel reduced and the sigmoid flexure again sutured in place. The patient then made an uninterrupted recovery. In the second case, which occurred almost at the same time, a similar sudden flow of serum soaking the dressing was noticed forty-eight hours after the operation. Unfortunately, the attendant did not realise the importance of this and it was not until some hours later, when the patient was "vomiting and partially collapsed," that the wound was uncovered. "All the bowel that could get out through a two-inch incision in the left inguinal region was out of the body and mixed up with the dressing." It took one hour and a half to separate the bowel and reduce it but the man sank under the shock of this operation. Dr Kelsey refers to accidents of an opposite character that have happened. The bowel in those cases slipped back into the abdomen and had to be picked up and secured again to the abdominal incision. These cases are worth

special attention because one advantage of inguinal colotomy over the lumbar operation is its extreme simplicity, and some surgeons have attempted to reduce its simplicity to the very lowest point by omitting all suture of the bowel to the abdominal wall and trusting only to a probe or some similar appliance thrust under the bowel through the meso-sigmoid. In view of these accidents it is quite evident that the bowel should be securely fastened to the abdominal incision in such a way as to prevent both its slipping back and the prolapse of further coils of bowel. Opinions may differ as to the best means of doing this. Probably none is better than a single stitch through the mesocolon and the skin on one side of the wound, one at each end through the longitudinal muscular band and both edges of the wound, and two interrupted sutures at each side passing through the muscular and serous coats of the bowel and the skin only.

THE PELLAGRA DEBATE IN THE ITALIAN CHAMBER

THE one blot on the generally satisfactory health conditions of Italy for the past twelve months was, as the official returns demonstrated, the pellagra—that frightful scourge, whose victims are chiefly to be found in Lombardy and Piedmont, and whose sequela, particularly in the third year from the initial attack, are seen in a paralysis, mental as well as physical, which contributes more inmates to the lunatic asylums than any other cause. Its etiology thanks not only to Italian but to French pathologists has been lately put on a more scientific basis than hitherto, and Dr H. Gintroc especially has differentiated it from the "pseudo pellagra," at least five in number, which mistaken for the true malady, have often led to mistakes in treatment and in prophylaxis. By the light of these researches it is of supreme importance that the profession at large and the sanitary authorities in particular should reconsider the means available for preventing as well as curing the disease, and so not a moment too soon, Signor Suardi Gianforte interpellated the Minister of Agriculture in the Italian Chamber as to what had been done and what it was still proposed to do by way of treatment in the public hospitals and of prophylaxis in the affected districts. He called attention to the vote carried in a former Parliament for the promotion of these therapeutic and precautionary measures, and he asked what success had followed them since their practical enforcement. As to the provisions for the prevention of the malady, he classified them in three groups: (1) That which improves the hygiene of the agricultural labourer by giving him better house accommodation, pure drinking water and better drainage, (2) that which comes to close quarters with his disease and provides sounder food at so-called cheap kitchens and also "locande sanitarie" or health stations, where he can be directly relieved of his more distressing symptoms, and (3) that remoter provision by which his life is made easier to him by better wages the lightening of taxes, reduction of octroi dues and such like. Under all of these heads there was still much to be effected before an impression, deep and lasting, was made on the pellagra whilst he admitted that group the second had—in the province of Bergamo for instance—yielded most satisfactory results which had also been exhibited on an encouraging scale in other provinces. But how to make the agricultural labourer do for himself what those cheap kitchens and health stations do so well though all of them too late? How to insure him a comfortable, well drained, well appointed dwelling and an increased wage or a remission of taxation sufficient to let him live and thrive? Such is the real problem, and its effective solution would mean the rehabilitation of the agricultural poor not in Italy only but in almost every country in Europe. Signor Suardi Gianforte concluded an eloquent

appeal for the Italian rural labourer by showing how much the State, in conjunction with the local proprietors and capitalists, could effect for him, and how the result of such action and legislation would be seen in the development of economic and social conditions which would make the pellagra impossible and the elaborate machinery organised to encounter it *une quantité négligeable*. His Excellency Signor La Cava (Minister of Agriculture) replied for the Government and pledged his department to continue its subsidies for the *essiccatoi* or furnaces for drying the maize and destroying the parasite that renders it noxious as food, whilst also maintaining the cheap kitchens and the health stations, "aiding and promoting, as it had hitherto done, the initiative of the private local charities." More important still, as an indication of policy, was his assurance that the Government would place funds at the disposal of provincial committees in aid of the "earning power" of the labourer, and, with this view, had already taken steps with the Lombard savings banks to furnish the subvention required. The "Opere Pie" (Italy's equivalent for State charities), he further suggested, might possibly, by transformations in their working, be made to yield more substantial aid than hitherto to the agricultural poor, and he concluded by reiterating the solicitude of the Government to minimise in the meantime and ultimately to stamp out at its origin the pellagra, which costs Italy so much in men and treasure. Altogether, the official reply was about as satisfactory as Signor Suardi Gianforte could have looked for—the heavy strain on the country's finances for the army and navy being considered. He accordingly accepted the Ministerial assurances with an expression of trust in their *bona fides*, of hope in their efficacy and of thanks for the fulness and cordiality with which they had been given.

"AKINESIA ALGERA"

UNDER this term Möbius¹ describes an affection of the nervous system characterised by extreme pain upon motion, so that the patient is unable to make any movement whatever. The exact pathological condition which is the cause of this symptom is as yet unknown. It appears only to occur in neurotic individuals, especially in those who are in a bad state of health generally and who are unable to fight against the weakness. The pain is sometimes directly associated with motion, but in other instances follows it, and is experienced not only in the parts of the body which have been moved but also in other parts, and may finally lead to almost complete loss of motive power, so that the patient is practically paralysed. In addition to this pain, which is the most prominent symptom, other phenomena characteristic of neurasthenia may develop, but hysterical outbursts have not been observed. Möbius considers that this disturbance may be attributed to inherited degeneration of the nervous system, that, as a rule, it follows upon mental strain in patients prone to neurasthenia, and that it must be regarded as a psychological affection. The condition must however be considered as more allied to hysteria than to hypochondriasis.

A SCOTCH PUBLIC HEALTH QUESTION

WE are glad to see that by a question in Parliament Dr. Parkerson has called attention to the subject of our last week's leading article, and that he proposes to take another opportunity of referring to it. The Secretary for Scotland gave a reply which cannot be regarded as satisfactory. He pointed out that under the Local Government Act county councils have power to permit their medical officers to engage in other work. That is not denied by anyone, but under the Local Taxation Act the Secretary for Scotland has power to

frame regulations for administration of the grant, and it is only reasonable to suppose that one of the regulations should be that counties must show to the Secretary that their sanitary arrangements are fairly satisfactory before he admits them to a share in it. It is this regulation, framed by his predecessor acting under the advice of the Board of Supervision, that Sir George Trevelyan seems to have decided to abrogate, and his decision is certainly unfortunate.

THE GRESHAM UNIVERSITY COMMISSION

THE proceedings of the Royal Commission appointed to consider the charter proposed for the formation of a new University in London, to be called the Gresham University, will immediately come to a close. Sir George Young and Professor Ramsay of University College have been heard, and Dr. Wace, the Principal of King's College, will be the last witness, and complete the evidence on behalf of the promoters of the Gresham Charter. We trust that the report of the Commissioners will be published as soon as possible.

PREVALENCE OF FEVER

DURING the week ended March 11th nearly 1100 cases of scarlet fever were reported in the chief towns of England. More than a third of these belonged to London. Liverpool, Manchester, Sheffield, Swansea and Leicester contributed most of the other cases. Some 300 cases of diphtheria were reported in the same time, the metropolis showing more than half of them. Manchester and Cardiff came next. Enteric fever prevailed most in London and Liverpool. It is pleasing to learn that the mortality from scarlet fever in London exhibits a distinct decline, and the number of patients in the fever hospitals is much less than a month ago. The diphtheria mortality remains much the same, but is still above the average.

HYSTERICAL RAPID RESPIRATION

IN the last number of the *American Journal of the Medical Sciences* Dr. Weir Mitchell has a paper dealing with this obscure and interesting affection. From his wide experience he is able to formulate a description of the symptoms associated with the condition. The breathing, he says, is largely upper costal, sometimes exclusively so, and the preservation of the relative share between that and the diaphragm is rare. As a rule it is superficial and without appearance of effort. Usually also, in the early stage the patient is ignorant of the existence of the symptom, but when once the knowledge is acquired the respiration rate is increased by excitement, such as is induced by the mere approach of the nurse or medical attendant. As a rule, too, the symptom occurs only just after sleep, and may be quite absent—indeed, usually is so—during sleep. Sometimes the symptom is the only distinct expression of hysteria or is not present unless the patient is emotionally excited, he does not moreover think that the type of breathing is a possible voluntary product, whilst he regards the affection in males as distinctly rare. Several cases are related which bear out this description, and amongst them one in which there was a curious and anomalous eruption on the leg somewhat rupial in character, which at first appeared as a mass of pimples. These, during a state of trance, became confluent and formed a scab, an excellent illustration of which is given in the paper. The scab was removed and under it there was found a greyish white fibrinous material, from the surface of which oozed a little blood. The skin round the edges was thickened, hardened and hyperæmic, and the area was very sensitive. Nothing else unusual was discovered in the patient's condition except a marked contraction of the colour fields, a chart of which is given. Reference is also made to different forms of rapid respiration, and graphic records of the varieties of these

are given. As was to be expected from the wide experience of Dr Weir Mitchell and his well known faculty of accurate observation, the paper is a very interesting one and calculated to assist in the elucidation of an obscure and unusual condition

ILLNESS OF PRINCE FERDINAND OF BULGARIA

WE understand that Prince Ferdinand of Bulgaria is suffering from an acute inflammation of the right middle ear, complicated with severe neuralgia of the occipital nerves. Professor Politzer has performed paracentesis of the tympanum. The patient is progressing favourably

FACULTY OF MEDICINE OF THE UNIVERSITY OF BRUSSELS

DR. WARWOTS having been appointed Professor of Operative Surgery, the Dean of the Faculty of Medicine of the University of Brussels has appointed Dr Albert Mills as interpreter for the examinations of British and American candidates who present themselves for the degree of M.D. Brussels. All applications concerning the examination should be sent to Dr Albert C. Mills, 25, Boulevard Bischoffsheim, Brussels

CENTENARY OF THE DEATH OF JOHN HUNTER

IN connexion with the conversazione to be held at the Royal College of Surgeons of England on July 5th, 1893, to celebrate the jubilee of the Fellowship of the College, it has been decided, as this year is also the centenary of the death of John Hunter, to organise an exhibition of pictures, MSS. books, furniture &c. connected with the great surgeon. In addition to the articles which are the property of the Royal College of Surgeons the exhibition will include other relics, the loan of which has been kindly promised by the present possessors. The Librarian of the College will be pleased to give further information to any owner of Hunterian relics who may be willing to lend them for exhibition

THE QUEEN'S VISIT TO FLORENCE

"OUR Lady of Flowers," writes an Italian correspondent under date Florence, 20th inst., 'has for some time been looking her best, as if in anticipation of the royal visit which will be an accomplished fact by the time this letter sees the light. Cloudless skies and a genial sun invite the resident out of doors and stimulate him to brisk exercise all the brisker as he feels the freshness, not to say sharpness, of the air wafted down by the *tramontana* from the Apennines. There is still snow on the more elevated peaks, which not as refrigerators and in the early morning and late evening impart a sting to the wind against which the pedestrian or the carriage inmate should guard. This is just the weather which, on the occasion of her last visit, Her Majesty most enjoyed—enjoyed, in fact, so much that the traditional cavillings at the treacherous Florentine spring' were rather silent during the Queen's *villeggiatura*. The interest taken by Her Majesty in most things Florentine includes many of the charitable institutions of the city and suburb, notably the admirable organisation of the 'Misericordia,' so often described in THE LANCET. That picturesque corps in which peer coöperates with peasant, scholar and artist with tradesman and mechanic, in relieving the sick, transporting them from residence to hospital, or, when medical art has proved abortive, conveying them to the mortuary chapel, is one of the most impressive features of daily life in Florence and merited the minute inquiries into its origin and working addressed by Queen Victoria to its titular chief. Then, again, Her Majesty's known solicitude for the better treatment of the lower creation is expected, as in 1888, to give a

salutary stimulus to the somewhat languishing 'Società' for the 'Prevention of Cruelty to Animals'—a 'società,' it is fair to say, much more efficacious in Florence than in Rome or Naples, but still, even in the former capital far short of the required efficiency. Another organisation in which the humanitarian instincts of the British Queen have quickened Florentine charity is that of the Society for the Protection of Abandoned Infants, and here again the promoters of the movement look to Her Majesty's presence and encouragement as effective influences for good. Concurrently with these special institutions for the relief of suffering, some notice is claimed for that other organisation, of which the leading consultants of the city are at the head, directing the operations of quite a little army of medical workers mostly students, for the treatment of patients too necessitous to be able to call in a regular practitioner. This charity, set on foot since Her Majesty's last visit and from time to time commented on in THE LANCET, is proud to claim the notice of a Sovereign who effectively promotes so many kindred charities at home and who derives no greater gratification than from the spectacle of the spread of the practical humanitarian spirit in the countries in which she sojourns. Public hygiene, too, seems to draw fresh encouragement from Her Majesty's presence. All the sanitary arrangements of the city, including the 'nettezza pubblica' (street scavenging), are already placed under more thorough and vigilant surveillance, and it is to be hoped that these salutary regulations will remain in force long after the immediate occasion that has evoked them has disappeared. As I write the Società Fiorentina d'Igiene has announced the proceedings of its last sitting at which the all important question of water supply was again discussed and practical suggestions were made for the speedy and effective creation of the new aqueduct which is to furnish Florence with a perennial provision of *acqua potabile*. Such are a few of the indications, interesting to the profession, which Her Majesty's approaching visit has called forth—indications which have their place side by side with the other incidents of the Queen's sojourn and explain in some measure the enthusiasm which that sojourn awakens in Italy's most educated city, anxious as it is to bring its social standard up to the British level."

PATHOLOGY OF PARALYSIS AGITANS

IN the *Zeitschrift für Heilunde von Ketscher* has an important paper dealing with this much disputed subject. An abstract of it is given in a recent number of the *Neurologische Centralblatt*. The cases of paralysis agitans with reference to their pathological anatomy, are divisible into two classes—those in which the examination has furnished negative results and those in which various changes have been found in the nervous system, such as hyperplasia of the connective tissue and neuroglia of the spinal cord, alterations in the nervous tissue itself and vascular changes. Similar changes have been described as occurring in the medulla and pons. Three cases of undoubted paralysis agitans have been investigated by von Ketscher. The nervous system, central and peripheral, was examined, and in all three cases changes were found in both regions. The nervous structures showed atrophy, the ganglion cells of the brain were deeply pigmented and altered in form, the nerve fibres, both in the peripheral nerves and in the spinal cord, were degenerated and had in some instances disappeared, whilst the muscular fibres also were atrophied or degenerated. The neuroglia was thickened especially around the vessels and mostly in the posterior and lateral columns. The vessels also were altered, their walls thickened and there were milary aneurysms and small hemorrhages present. Similar changes but slighter in degree, were found as senile changes in patients not the subjects of paralysis agitans. von Ketscher concludes with Borgherini and others, that paralysis agitans is only the expression of an extreme and

appeal for the Italian rural labourer by showing how much the State, in conjunction with the local proprietors and capitalists, could effect for him, and how the result of such action and legislation would be seen in the development of economic and social conditions which would make the pellagra impossible and the elaborate machinery organised to encounter it *une quantité négligeable*. His Excellency Signor La Cava (Minister of Agriculture) replied for the Government and pledged his department to continue its subsidies for the *essiccatori* or furnaces for drying the maize and destroying the parasite that renders it noxious as food, whilst also maintaining the cheap kitchens and the health stations, "aiding and promoting, as it had hitherto done, the initiative of the private local charities." More important still, as an indication of policy, was his assurance that the Government would place funds at the disposal of provincial committees in aid of the "earning power" of the labourer, and, with this view, had already taken steps with the Lombard savings banks to furnish the subvention required. The "Opere Pie" (Italy's equivalent for State charities), he farther suggested might possibly, by transformations in their working, be made to yield more substantial aid than hitherto to the agricultural poor, and he concluded by reiterating the solicitude of the Government to minimise in the meantime and ultimately to stamp out at its origin the pellagra, which costs Italy so much in men and treasure. Altogether, the official reply was about as satisfactory as Signor Suardi Gianforte could have looked for—the heavy strain on the country's finances for the army and navy being considered. He accordingly accepted the Ministerial assurances with an expression of trust in their *bona fides*, of hope in their efficacy and of thanks for the fulness and cordiality with which they had been given.

"AKINESIA ALGERA"

UNDER this term Möbius¹ describes an affection of the nervous system characterised by extreme pain upon motion, so that the patient is unable to make any movement whatever. The exact pathological condition which is the cause of this symptom is as yet unknown. It appears only to occur in neurotic individuals, especially in those who are in a bad state of health generally and who are unable to fight against the weakness. Whistler, Esq, M.D.

On Friday, the 17th inst. Professor Virchow was enrolled as an Honorary Fellow of the Irish Medical Schools and Graduates Association. We report the proceedings in detail in another column.

At a special congregation of the University of Cambridge held on Tuesday, the 21st inst., the degree of Doctor of Science *honoris causa* was conferred upon Professor Virchow. The following was the speech delivered by the Public Orator — "Dignissime domine, domine Procancelarie, et tota Academia Universitatis Berolinensis Rector Magnificus vir non modo de medicina et salute publica, sed etiam de anthropologia, de ethnologia, de archaeologia præclare mentus, vir et sexagesimo et septuagesimo exacto ætatis anno honoribus amplissimis cumulatus satis magnum hodie præbet di cendi argumentum. Ipselaudenostremaior, laudes tamen suas (qua est modestia) invitus audiet, atqui laudes illas non verba nostra qualiacumque, sed ipsius opera insignia, ipsius discipuli illustres ipsius denique orationes disertissimæ, etiam ipso invito satis clare loquuntur. Legistis fortasse orationem illam in qua, Rectoris munus nuper auspicatus, studiorum Academicorum orbe universo lustrato, partium liberalium dux et signifer olim insignis dixit veram Academicæ libertatem esse libertatem docendi, libertatem discendi, ostenditque, qua potissimum mentis disciplina inventus Academicæ discendi amore vere liberali imbui posse videretur. Legistis certe, fortasse etiam audivistis orationem alteram in qua nuper inter scientias biologicas locum pathologiæ proprium vindicavit, et, studiorum suorum origines repetens, non modo Harveii nostri merita immortalia denuo commemoravit, sed etiam Glissonii nostri gloriam prope intermortuam ab integro renovavit. Harveii quidem in doctrina, omne rerum ex ovo nasci, lacunam magnam relictam esse constat, letamur lacunam tantam ab eo magnâ ex parte esse expletam qui primus omnium re vera probavit omnem cellulam e cellula generari. Ergo rerum naturæ in vestigator tantus, tot illustrium præsertim medicorum in Academia, titulo nostro honorifico iure optimo decoratur. Etenim ubicumque florent medicinæ studia cum rerum nature observatione exquisita feliciter conjuncta, talium virorum nomina in honore maximo non immerito habentur. Talium certe virorum per labores verba illa vetera vera facta sunt,

quæ Salutis in templo supra portam inscripta esse debent — *sine rerum naturæ cognitione trunca et debilis est medicina*. Duco ad vos Regiæ Societatis Londinensis unum e focus extraneis, virum gentis Teutonicæ inter decora numeratum, RUDOLPHUM VIRCHOW."

On the 23rd inst. the honorary degree of D.C.L. was conferred upon our distinguished visitor by the University of Oxford.

A CRITICAL EXAMINATION OF THE SO-CALLED "LEICESTER SYSTEM" OF ISOLATION AND QUARANTINE

BY A. T. BREMNER, L.R.C.S., L.R.C.P. EDIN.,
MEMBER OF THE LEICESTER FEVER HOSPITAL COMMITTEE.

THE present outbreak of small pox in Leicester began in the early part of September, 1892, and the time is now opportune to enter into a critical review of the "Leicester method", to compare facts which can be adduced in its favour with those other facts which tend towards its discredit, and to throw the full light of day upon this "system" with all its faults and failings. As a preface it may be remarked as a singular coincidence that the pæans of praise which are sung in season and out of season on behalf of this much vaunted system proceed out of the mouths of members of the anti vaccination party. The supposed brilliant results of the Leicester system have been appropriated by them as the strongest available argument in favour of their peculiar tenets, and these results are set forth for the admiration of an incredulous world as an "object lesson" to be worthily imitated by less enlightened communities. We are asked to gaze upon the "marvellous success" which has enabled Leicester to stamp out small pox on every occasion (except the present one), and to note that this success is obtained without recourse to vaccination. It is somewhat difficult to obtain any clear definition of what the Leicester method really is. For my purpose it will be sufficient to quote the description given by Mr J. T. Biggs, a member of the Leicester town council, and it is needless to say a leader of the anti vaccination movement. Writing in the *Vaccination Inquirer* on Nov 1st, 1892, he says "The marvellous success which for the past twenty years has attended the efforts of the sanitary authorities at Leicester in stamping out small pox without recourse to vaccination is now universally known and admitted. What is known as the 'Leicester method' is now adopted and practised by almost all sanitary authorities everywhere, whether they do or do not profess to believe in the efficacy of vaccination, but from the original 'model' there has been considerable departure by would be imitators. That which in Leicester has become part of the life of a free people has in many other places, in the hands of irresponsible authorities guided by medical interference and prejudice, become an engine of despotic power. What, then, is really our procedure on the notification of a case of small pox? This will, perhaps, be best described in the identical words of our chief sanitary inspector. 'When a case is reported I at once go to the infected house and try to ascertain where the disease was contracted, where the patient has been working, where he has been visiting, and his movements generally for the last ten or twelve days. I also make a point of seeing all persons who have visited the infected house during the time stated, in addition, I visit all factories and workshops where other members of the family have been employed, and by this means have been able to get cases removed when the first symptoms of the disease appeared. Immediately on the removal of the patient I superintend the fumigation of the house with sulphur, liquid disinfectants are used freely in the drains and about the yard, and the ashpit is emptied and disinfected, the next day the bedding is taken to the disinfecting chamber and subjected to the hot air process. Up to the present time I have succeeded in getting almost every person connected with the infected houses into quarantine in a very few cases I have experienced opposition.'"

It is at once apparent that there is no novelty in this, except in the exclusion of vaccination from the means employed, and with the definition as it stands I find no fault, but I must call attention to the very evident fact that isolation as a means of preventing the spread of small pox and other infectious diseases has long been recognised as of the

premature senility of the nervous system, and he is of opinion that the primary changes are in the vessels, those in the nervous structures being secondary

THE HEALTH OF LORD SALISBURY

WE are glad to be in a position to state that Lord Salisbury is steadily recovering from his attack of influenza.

MEDICAL AID ASSOCIATIONS AND THE GENERAL MEDICAL COUNCIL

WE understand that the committee on Medical Aid Associations sat on Friday for seven hours. Six or seven lay representatives of the Associations attended and gave evidence of the working of such institutions, including secretaries or presidents of the Associations at Wolverhampton, Lincoln, Northampton, Luton and Gloucester.

THE SCOTCH FORM OF OATH

THE Home Secretary, Mr Asquith, replying to Dr Farquharson in the House of Commons on the 13th inst., stated that circulars containing the necessary information as to the correct form of administering the oath would be sent to all justices' clerks and coroners. It may be well to point out that similar circulars will have to be sent in respect of grand juries, since we learn from a correspondent that, on his application to be sworn with uplifted hand before a grand jury, the foreman, whose duty it was to administer the oath, was unaware of the form. Fortunately our correspondent had it and was duly sworn. The various high sheriffs of the counties would probably be the readiest medium by which the requisite information could be conveyed.

THE Royal Commission on Vaccination met on Wednesday in Great George street, under the chairmanship of Sir Richard Paget, in the absence of the Lord Chancellor. Dr Klein and Dr William Ogle, Superintendent of Statistics in the office of the Registrar General, gave evidence, and the Commission adjourned over the Easter recess.

MR. BERNARD PITTS, M.Ch.Cantab. & F.R.C.S., Senior Assistant Surgeon to St. Thomas's Hospital, has been appointed Joint Lecturer on Surgery in the Medical School in succession to Sir W. Mac Cormac.

THE Right Hon. Thomas H. Huxley, Hon. D.C.L. Oxon., F.R.S., F.R.C.S. &c., will deliver the Romanes Lecture at the University of Oxford on Thursday, May 18th.

PROFESSOR VIRCHOW

SINCE his arrival in England to deliver the Croonian Lecture of the Royal Society Professor Virchow has been the recipient of many honours. On the evening of Thursday, March 16th, he was entertained at a banquet, at which Lord Kelvin presided. We regret that we have been unable to provide our readers with an elaborate account of the proceedings of a meeting the successful nature of which was due in great measure to the interest taken in it by members of the medical profession and to their attending in large numbers to do honour to their eminent German confrere. The committee of management curiously enough decided not to invite representatives of the medical press to the banquet. It is incomprehensible that a body of managers should take advantage of the services of the medical press for the purpose of bringing the proposed banquet under the notice of the profession and should have neglected to invite the representatives of the organs of the profession, although it would appear that the daily papers were furnished with facilities for reporting the proceedings in their columns. We are sorry to have to strike one discordant note

on such a harmonious occasion, but we feel that in the interests of the profession the matter should not be allowed to pass by without a few words of protest.

We append the list of the stewards who took part in the banquet given in honour of Professor Virchow on March 16th, 1893.—W. H. Allchin, Esq., M.D., C. Arkle, Esq., M.D., J. Andrew, Esq., M.D., Sir Henry Acland, Bart., K.C.B., W. Anderson, Esq., F.R.C.S., W. H. Broadbent, Esq., M.D., Sir James Crockett Browne, LL.D., F.R.S., T. Bryant, Esq., President of the Royal College of Surgeons, R. Baines, Esq., M.D., A. T. Brett, Esq., M.D., H. C. Bastian, Esq., M.D., F.R.S., F. Gordon Brown, Esq., President of the Hunterian Society, J. S. Bristowe, Esq., F.R.S., President of the Medical Society, Hamilton Bland, Esq., M.D., Stanley Boyd, Esq., F.R.C.S., F. G. Barford, Esq., M.D., Lauder Brunton, Esq., M.D., F.R.S., A. E. Barker, Esq., F.R.C.S., T. Bridgwater, Esq., LL.D., W. Bennett, Esq., F.R.C.S., R. Bowles, Esq., M.D., R. Barwell, Esq., F.R.C.S., Adolph Bronner, Esq., M.D., David Berry, Esq., Surgeon Captain R. Ashton Bostock, Sir George Buchanan, M.D., B. E. Brodhurst, Esq., F.R.C.S., C. Beever, Esq., M.D., Lionel Beale, Esq., M.D., R. A. Bickersteth, Esq., F.R.C.S., M. Carteghe, Esq., President of the Pharmaceutical Society, Sir Andrew Clark, Bart., President of the Royal College of Physicians and of the Royal Medical and Chirurgical Society, D. M. Crookshank, Esq., M.B., Sir Thomas Crawford, K.C.B., W. Corfield, Esq., M.D., J. Canavy, Esq., M.D., J. Cox, Esq., M.D., Surgeon General Cornish, C.B., J. Cagney, Esq., M.D., J. Couper, Esq., F.R.C.S., H. Clutton, Esq., F.R.C.S., W. S. Church, Esq., M.D., R. Brudenell Carter, Esq., J. Curnow, Esq., M.D., S. Coupland, Esq., M.D., W. Cheadle, Esq., M.D., F. H. Champneys, Esq., M.D., T. F. Chavasse, Esq., M.D., J. Jackson Clarke, Esq., F.R.C.S., Alfred Cooper, Esq., F.R.C.S., G. Anderson Critchett, Esq., F.R.C.S. Edin., Sir Dyce Duckworth, M.D., LL.D., W. H. Dickinson, Esq., M.D., Sir William Dalby, F.R.C.S., Arthur Durham, Esq., F.R.C.S., Frederick Durham, Esq., F.R.C.S., N. Davies Colley, Esq., F.R.C.S., A. H. Doran, Esq., F.R.C.S., C. T. Dent, Esq., F.R.C.S., J. J. Dunbar, Esq., M.D., S. Delépine, Esq., M.D., Norman Dalton, Esq., M.D., W. R. Dakin, Esq., M.D., W. Day, Esq., M.D., James Davison, Esq., M.D., James Duncan, Esq., M.D., G. Eastes, Esq., F.R.C.S., G. Elder, Esq., M.D., A. Eddowes, Esq., M.D., Sir John Evans, Professor Michael Foster, M.D., F.R.S., Sir Walter Foster, M.D., M.P., Sir Joseph Fayrer, K.C.S.I., M.D., R. Farquharson, Esq., M.D., M.P., R. Flachs, Esq., M.D., O. H. Fowler, Esq., M.D., H. M. Fletcher, Esq., M.D., Willoughby Turner, Esq., M.D., David Ferner, Esq., M.D., F.R.S., W. H. Forsbrook, Esq., M.B., J. F. Goodhart, Esq., M.D., J. Glover, Esq., M.D., Sir Archibald Geikie, LL.D., Foreign Secretary of the Royal Society, A. Pearce Gould, Esq., F.R.C.S., W. C. Grogg, Esq., M.D., John Gay, Esq., C. Golding Bird, Esq., F.R.C.S., R. J. Godlee, Esq., F.R.C.S., C. Godson, Esq., M.D., W. R. Gowers, Esq., M.D., F.R.S., H. Gervie, Esq., M.D., J. H. Gladstone, Esq., Ph.D., F.R.S., G. Harley, Esq., M.D., F.R.S., Sir G. Humphry, M.D., F.R.S., President of the Pathological Society, E. Hart, Esq., F. Hawkins, Esq., M.B., G. E. Herman, Esq., M.D., J. Hutchinson, Esq., F.R.S., J. Hutchinson, Esq., jun., F.R.C.S., Roger J. Hutchinson, Esq., M. Handfield-Jones, Esq., M.D., Victor Horsley, Esq., F.R.S., R. Harrison, Esq., F.R.C.S., W. Hunter, Esq., M.D., T. C. Hayes, Esq., M.D., Donald Hood, Esq., M.D., R. J. Bliss Howard, Esq., F.R.C.S., W. A. Hollis, Esq., M.D., W. H. Hamer, Esq., M.D., the Right Hon. Thomas Huxley, LL.D., D.C.L., Charles Higgins, Esq., F.R.C.S., Sir George Johnson, M.D., F.R.S., H. Juler, Esq., F.R.C.S., Brigade-Surgeon Johnston, Lord Kelvin, President of the Royal Society, Norman Kerr, Esq., M.D., E. Klein, Esq., M.D., A. A. Kanthack, Esq., F.R.C.S., J. S. Keeser, Esq., M.D., F.R.C.S., A. L. Kellgren, Esq., M.D., J. A. Kingdon, Esq., F.R.C.S., J. G. Douglas Kerr, Esq., M.B., J. B. Lawford, Esq., M.D., P. W. Latham, Esq., M.D., Sir Trevor Lawrence, Bart., Sir Joseph Lister, Bart., F.R.S., John Langton, Esq., F.R.C.S., David Little, Esq., M.D., James Little, Esq., M.D., Edward Law, Esq., M.D., Malcolm Morris, Esq., F.R.C.S. Edin., President of the Harveian Society, Sir William Mac Cormac, F.R.C.S., Shirley F. Murphy, Esq., F. J. Mount, Esq., M.D., LL.D., S. Mills, Esq., A. T. Myers, Esq., M.D., Howard Marsh, Esq., F.R.C.S., A. B. Myers, Esq., M.D., Allan MacIndyn, Esq., M.D., Sidney Martin, Esq., M.D., Norman Moore, Esq., M.D., J. A. McIntyre, Esq., M.D., W. Marceet, Esq., M.D.,

to be revaccinated. This person fell ill with the disease in due course and was admitted to hospital. It is incorrect to say that quarantine is carried out without recourse to vaccination and revaccination. True, vaccination is not put into practice as it ought to be, and much which should be done in this direction remains undone, to the continued peril of the public safety.

COMPENSATION OR NO COMPENSATION?

In the article of Mr Biggs referred to above, he says "Another baseless assumption that is frequently used for the purpose of discrediting us is that this Leicester method of isolation, quarantine, disinfection and sanitation is so excessively expensive as to be practically prohibitive. Now, I can show, on the contrary, that our Leicester method is extremely economical as well as effective. Besides, it is now well known that however thoroughly a community is vaccinated, so little reliance is placed upon this supposed safeguard that on the outbreak of small pox recourse is at once had to the very measures which have been so persistently decried when used to the salvation of unvaccinated Leicester. Comment from me is unnecessary, further than to say that compensation for loss of time is not offered, but if, as a precautionary measure, bedding or clothing have to be destroyed, their value is made good." When the "little bill" for compensation for loss of time and for carrying out the other details of the Leicester system is produced it will present a sufficient commentary on this statement. The heavy expenses already incurred may afford an instructive object lesson to all students of sanitation, but will bring small comfort to the already overburdened ratepayers of Leicester. It is not long since one of these so-called "quarantine" persons walked into the presence of the sanitary committee (to the consternation of some of the members) to complain of the £1 a week awarded him as being insufficient, and, like Oliver Twist, he had called to "ask for more."

In face of these facts I ask, "What has become of the Leicester system? The present hospital and its quarantine arrangements are utterly inadequate and have failed in their professed purpose, as has been pointed out again and again in THE LANCET. The hospital can not be regarded as an isolation hospital at all, for with the first small outbreak of small pox it is necessary *volens volens* to clear out all the fever cases. To-day no cases are admitted excepting those of small pox, and the quarantine at the hospital is actually empty. The majority of persons who have been exposed to contagion are now subjected to a process of surveillance at their own homes, and in this way it is proved that this so-called 'system' is nothing short of lack of system. The fact is self-evident to every unbiased mind that we have been living in a fool's paradise, and that an outbreak of small pox of moderate dimensions has been sufficient to prove that Leicester, so far as hospital accommodation and provision for isolation and quarantine are concerned, was ill prepared to cope with the disease. In fact, Leicester at the time of the outbreak of small pox was probably as little prepared to meet it as any other large town. Our recent experiences may perhaps teach us a useful lesson, and when we have provided that hospital accommodation for infectious disease of which we stand so sorely in need, when we have supplied means of isolation and quarantine in practice and not in theory, when we have adopted vaccination and revaccination as our first line of defence—then, and then only shall we be able to claim that the 'Leicester system' is a method worthy of imitation and not a fantastic phrase which means nothing

CHOLERA.

RUSSIA has of all countries suffered most severely from the epidemic. Its geographical position led to its being earliest attacked and the epidemic has continued, more or less with varying degrees of intensity up to the present time. During the latter half of February 305 cases of cholera with 59 deaths occurred in the province of Podolia, and according to the latest reports from St. Petersburg the disease is said to be spreading over Central Russia. The peasants are, it is stated, dying by thousands and the greatest distress prevails through-

out the whole region. The governments most severely visited by the epidemic are Astrachan, Ekaterinoslav and Moscow. Isolated cases of cholera have also occurred during the present month in the towns of Nijni Novgorod, Orel, and Yaroslavl and in the province of Kieff. In view of the possible outbreak of cholera in the Trans-Caspian Province it has been decided, as a precautionary measure, to establish a sanitary cordon on the frontier of Khorassan and Afghanistan. Moreover the Minister of Ways and Communications is about to make a sanitary inspection of all the Russian railways. A congress of sanitary officers will meet at St. Petersburg shortly to consider the measures to be taken in the event of a general reappearance of cholera this spring and in the coming summer.

From L'Orient (Brittany) we learn that many cases of cholera have appeared during the present month. Six deaths occurred in eight days among patients presenting choleraic symptoms, and on the 16th inst. it was stated that four fresh cases had occurred.

In connexion with these facts it is interesting to note that frequently the earliest indications of an epidemic spread of cholera in India outside its endemic area are the occurrence of sporadic cases in various places or localised outbreaks on a small scale in March and April, and the disease has been named in consequence spring cholera, to denote the season of its prevalence.

As regards the proceedings of the International Sanitary Conference, it is believed that these have been confined to the discussion of general questions. According to the special correspondent of *The Times*, there is a general impression that the delegates from the greater number of the Powers concerned will endeavour to remove or minimise, as far as practicable, restrictions on traffic and commerce, and that their efforts in this direction will be supported by the delegates from this country and aided by the influence of some of the scientific experts from Germany and the Continent in general.

THE PROPOSED MEDICAL SCHOOL AT CARDIFF

ANOTHER step forward has been taken by the Council of the University College of South Wales and Monmouthshire towards the establishment of the projected School of Medicine at Cardiff in connexion with the College. Last week Dr A. W. Hughes was appointed Professor of Anatomy and Dr J. Berry Haycraft Professor of Physiology, and it is expected that the formal opening of the school will take place in October next. Both these gentlemen are well known as teachers and investigators in their respective subjects, and, having already had considerable experience in the teaching and the organising of teaching in medical schools, will considerably strengthen the scientific branches of the professorate of the University. We congratulate South Wales on obtaining the services of such well trained professors for their new chairs, but we cannot avoid pointing out that salaries of £350 per annum, without a share of the fees paid by their students, are quite insufficient to retain their services for any period of time should they be offered similar chairs in other medical schools. Cardiff boasts of its goodly list of scientific institutions, but it will scarcely urge that its liberality in endowing professorial chairs is also a feature of which it may be justly proud. The University College of South Wales has been very successful in passing its students at the Preliminary Scientific M.B. Examination at the University of London, and this new departure will enable it to teach students for the intermediate M.B. examination and for the second examination of the Conjoint Board for England and for the corresponding scientific examinations of the other licensing authorities. We have no doubt that all this work can be well done at provincial centres of education, provided the teachers and the material are forthcoming as they should be at a place of the size, position and importance of Cardiff. It is just possible that there may be some difficulty with regard to the practical instruction in anatomy, but this will mainly depend on the size to which the proposed school will ultimately attain. In addition to the more strictly scientific part of the curriculum,

highest importance. It is not peculiar to Leicester, on the contrary, such means for isolation are supplied by the sanitary authorities of every large town in the kingdom and of many rural districts, and are carried out in many towns more rigorously and more efficiently than in Leicester. I may here express my ardent appreciation of the principle of isolation and quarantine, with the distinct proviso that this principle to be effectual must be carried out on rational and scientific lines. It is puzzling to ascertain why any special credit should be taken for this procedure when we reflect that the advantages of isolation have been known from an early period of the world's history, and were appreciated even in the year B.C. 1490. This period being somewhat antecedent to the anti vaccination movement, the statement of the above historical fact disposes of any pretensions to originality which may be advanced. It will thus be seen that so far only those ordinary measures are put in force which are adopted by all careful sanitary authorities, there is, in fact, nothing original in the means employed.

The essential point in which the Leicester system differs from all other systems consists in the claim which is put forth by its advocates with tireless reiteration, that the sanitary measures I have named are sufficient to stamp out any outbreak of small pox which may arise without recourse to vaccination.

To again quote Mr Biggs from the article named above "Vaccination has rapidly declined in the borough, now being only about 2 per cent of the births, and small pox mortality has disappeared from our midst." No comment is necessary, except to state the simple fact that since Sept. 7th, 1892, 132 cases of small pox have occurred and ten persons have died in Leicester of that disease. If we were disposed to consider in a serious light the extravagant pretensions which are claimed for the success of the Leicester method by certain misguided enthusiasts we might almost be persuaded that we had reached a state of sanitary perfection. It is true that large sums have been spent—and very properly spent—in putting Leicester into a good sanitary condition, and the highest praise is due to the town authorities for their excellent results in this direction. The immense outlay has already been rewarded by an improved state of the public health, and the lowering of the death rate is in a great measure due to this wise expenditure. It will however, scarcely be credited that the decreased death rate from all causes is not attributed to the true reason named above, but, practically, to the abandonment of primary vaccination. We have been accustomed to hear these loud voiced laudations of the Leicester system cried from the housetops during those times when the town has fortunately been free from small pox, but the tune is now pitched in a minor key, as public opinion is awakening to the fact that on this first occasion on which the system has been fairly tested it has been tried and found wanting. It would naturally be inferred by outsiders that the means employed are perfect in their character and the organisation used unrivalled in its method, that we have reached a degree of excellence which places Leicester above all other towns in its special mode of dealing with small pox isolation and quarantine, that in our capacity as "superior persons" we wish to demonstrate to the world how to do it and how not to do it, and, lastly, to show that these wondrous results are gained because we have a free hand, unfettered by "medical interference and prejudice," and that our success is reached with out any resort to that "medical superstition"—vaccination.

PROVISION FOR ISOLATION IN LEICESTER.

The Leicester Fever Hospital was constructed in an emergency for the reception of small pox cases, and so long as it was reserved for that end it fulfilled a useful purpose. With the disappearance of the small pox epidemic of 1871-72 it gradually became a hospital for infectious diseases generally. For many years it has been chiefly used for the reception of scarlet fever cases, the three principal wards being devoted to this purpose. These wards open into a common corridor, possess each a small side room and on the opposite side of the corridor, and also opening into it are the various rooms connected with the administrative department. At the western extremity of the main building, and at right angles to it, is the small pox block. The end of this block is within ten feet of the main building, and this fact is sufficient to condemn the hospital from the point of view of isolation. At the eastern end of the hospital site is a block known as the "erysipelas ward," so called because it scarcely ever contains an erysipelas patient. This ward in its time

has played many parts, and at the period when small pox appeared in the fever wards was full of convalescent scarlet fever cases. These children were then sent to their homes, and the erysipelas or convalescent fever ward was at once transformed into a quarantine building, forming the next stage in the "object lesson" which we are invited to admire. It will thus be seen that when small pox broke out in the overcrowded fever wards, with the exception of the small side rooms which form an integral portion of, and communicate directly with, the large wards, there was not in the whole hospital a single room which could be appropriated to the observation of a doubtful case.

NURSES' ACCOMMODATION.

During the course of the present outbreak of small pox one of Humphreys' buildings has been erected for the separate use of nurses engaged in the small pox ward. Up to this time the nurses engaged in this duty were compelled to sleep and take their meals in the same building in which the patients were placed. Owing to lack of accommodation on the premises certain officials of the institution have been accustomed to sleep at their homes in the town, thus constituting a serious danger to the public safety. One of these (a laundrywoman) was actually attacked with small pox and admitted to the Small pox Hospital as a patient where, I regret to say, she afterwards succumbed to the disease. Is it not a sad reflection on the "Leicester system" of isolation and quarantine that such laxity of arrangements is permitted to prevail in respect of the hospital attendants, whilst at the same time insisting upon the necessity of quarantine so far as private individuals are concerned?

QUARANTINE ARRANGEMENTS.

Two small rooms directly communicating with each other and with a passage in the main building are known as the "old quarantine." These rooms are in close contiguity to the fever wards and are not far removed from the small pox block. So long as we have had only an odd case or two of small pox to deal with these rooms have sufficed for the object in view and have formed the mainstay of our system of quarantine. It is hardly necessary to point out that the position of these rooms has been a source of continual danger to their inmates. The large erysipelas (?) ward is now used for quarantine purposes and is as cheerless a habitation as can well be imagined. In this building live the persons who have consented to do their "fourteen days'" observation. I must here acknowledge that these people are treated with every consideration so far as is compatible with deprivation of liberty, and that they are supplied with all the necessaries of life in the form of good food, together with some of its luxuries in the shape of tobacco and beer. On Oct. 31st, 1892, the hospital was more than full, containing 158 patients suffering from scarlet fever. Of this number 84 were vaccinated, including those vaccinated by the medical officer of health. Of these 84 vaccinated children not one contracted small pox. The remaining 74 were unvaccinated, 13 of these contracted small pox and 4 died. Small pox having broken out amongst these children it became necessary to send the remaining scarlet fever cases to their own homes, where they were kept under observation, and some of them were readmitted to the hospital suffering from small pox.

The recital of a few prominent facts regarding quarantine will be sufficient to show that it is not so rigorous as is represented, that it is, indeed, of the most elastic character. It consists of at least four varieties. 1. Small pox patient removed to hospital and all inmates of house to quarantine. 2. Patient removed but other inmates left at home, "compensation" being awarded to induce these persons to keep from work. 3. Patients from public institutions—e.g., infirmary, workhouse and also from common lodging houses—are removed to hospital, and the other inmates are daily inspected to see how they are "getting on." 4. Patients not removed to hospital and other inmates not removed to quarantine. During the present outbreak, so far as it has gone, 205 persons have been quarantined at the hospital, whilst 723 have been watched at their own houses or at work houses, or in common lodging houses. The contrast between these figures is most significant, and is largely due to the fact that small pox broke out in public institutions and lodging houses, the inmates of which it was clearly impossible to quarantine at the hospital. Quarantine being a voluntary act, "part of the life of a free people" in October we met with the first refusal in the case of a person who absolutely declined to enter hospital quarantine and as firmly declined

IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION

THE annual meeting of this Association was held on St. Patrick's Day, March 17th, at the Medical Society's rooms, Chandos-street. The chair was taken by Sir Thomas Crawford, K.C.B. Special interest attached to the occasion, as the Association was honoured with the presence of Professor Virchow of Berlin, who had responded to the desire of the council to elect him as an honorary member.

Sir THOMAS CRAWFORD said the honour of introducing Professor Virchow to the Society had unexpectedly fallen upon himself in the absence of their senior Vice President, Dr. Macnaughton Jones. Professor Virchow had already received a hearty and cordial reception from the members of the profession in London, but, although they were a smaller body, in no portion of the medical society of London could he be more warmly appreciated or more heartily esteemed than he was in the Irish Graduates' Association. Addressing Professor Virchow, Sir Thomas Crawford said he had great pleasure in being enabled to enrol his name as an honorary member of the Association, and also in re-echoing what was so ably said at the Hotel Métropole banquet as to the manner in which his distinguished services to the profession had been appreciated, not only in his own country, but also throughout the whole civilised world.

Professor VIRCHOW expressed his gratification at meeting such an honoured body of graduates from the Green Isle. It had long been his wish to visit that country, but it had been hitherto impossible for him to accept the invitations he had received from Dublin. He hoped they would accept his hearty thanks for the reception they had accorded him and convey his good wishes to their confreres. He spoke of the esteem with which the degrees conferred by Trinity College were regarded in Germany and of the high reputation borne by the Irish medical schools. Professor Virchow then inscribed his name on the roll of members.

The CHAIRMAN said the Association had also had the privilege of enrolling Sir James Paget as one of its honorary members. Sir James Paget was not an Irish graduate in the Irish sense of the term, but he was a graduate of every college and university which respected itself, and, like Professor Virchow, he enjoyed the honour of the world at large.

Professor Virchow then left amidst renewed demonstrations of applause.

The minutes of the previous annual meeting having been confirmed,

Dr. CAGNEY (hon. sec.) read the sixteenth annual report, which stated that the present total strength of the Association was 701. It was now the second largest association of medical men in the English dominions, and, consisting entirely of Irishmen or of those who had the interests of Irishmen at heart, it should have great weight in deciding the course of events which bore directly upon the reputation of the Irish schools and upon the fortunes of Irish practitioners at home and abroad. This reputation and these fortunes had become the special care of the Association. The exclusion of Irish and Scotch diplomats from honorary appointments on the staff of certain English hospitals was referred to, and the Association was resolved to spare no pains to procure the abolition of the anomaly. An attempt had also been made to induce the medical authorities of the chief London hospitals to reconsider their policy, and the council was not without hope that they might in time come to hold the more liberal view which experience had shown to be that generally taken by the charitable public whom they represented. It had been ascertained further that Guy's and University College Hospitals, as well as St. Mary's Hospital, repudiated the necessity for restriction of any kind. On the other hand, there was one hospital at which the highest degrees of the Irish and Scotch Universities were expressly rejected and an English degree was required, as well as an English diploma, from candidates who sought an appointment upon its staff.

Dr. MAROTER moved the adoption of the report, which was seconded by Dr. W. H. BOURKE and agreed to.

On the motion of Dr. MAROTER, seconded by Dr. WELLS, it was agreed to elect Dr. Richard Heath as president-elect for the forthcoming year.

Sir Thomas Crawford, Dr. Macnaughton Jones, Professor McAlister and Dr. Fernin were elected as vice-presidents, after which the usual votes of thanks were passed.

The following members were elected as the council for 1893-94.—Dr. P. S. Abraham, Dr. W. A. Carte, Dr. J. Davison, Mr. P. C. Hayes, Mr. C. H. Hartt, Mr. J. J. Lough, Dr. H. H. E. Phillips, Dr. F. J. A. Waring, Mr. W. D. Waterhouse, Dr. W. H. White, Dr. W. Barter, Mr. W. Stoker, Dr. T. M. Dolan, Mr. G. Stoker, and Mr. R. J. Swan.

The annual dinner of the Association took place the same evening at the Holborn Restaurant. Sir T. Crawford, K.C.B. (in the chair), was supported by Sir Walter Foster, M.P., Sir William MacCormac, Dr. Gilbert Smith, Dr. Mapother and others, and the guests included the Dean of Norwich, Professor Clifford Allbutt, Dr. Ferner, F.R.S., Mr. MacKellar and others. The usual loyal toasts having been given, the Dean of Norwich spoke for the visitors. Dr. Ferner proposed the "Health of the Association," and Dr. Crawford Hayes that of the "Universities and Corporations," to which Professor Clifford Allbutt replied. An excellent programme of music, to which Mr. J. G. Robertson and Mr. Cheesewright contributed, added to the success of the evening.

THE SEVENTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY

THE Transactions of this Congress are now being distributed by Messrs. Eyre and Spottiswoode, who have acted as its printers and publishers. The time which has elapsed since the close of the Congress (August, 1891) is considerable, but no one who is acquainted with the difficulties and delays necessarily involved in dealing with manuscripts in foreign languages and in transmitting proofs to almost all parts of the world will feel inclined to seriously complain of any delay in issuing these thirteen volumes, extending collectively to something like 3400 pages and amounting in the mass to more than fourteen tons of printed matter. The Transactions are considerably more bulky than those of any of the previous Congresses, and as each section has a volume to itself it is easy to find those matters in which the reader may have a special interest. Dr. Shelly of Hertford, who has acted as Editor for the Congress, is certainly to be congratulated upon the successful termination of his heavy labours. Each volume has a good index, and in the final volume (Miscellanea, vol. xiii.) will be found not only an index of authors but the index of each of the other volumes as well, so that to find any particular paper or discussion it is only necessary to take one volume from the shelf. The volume devoted to Miscellanea contains, in addition to indices, the list of members and delegates (British, foreign and colonial), the names of the institutions, municipalities &c. which sent delegates to the Congress, the list of donors, and also complete lists of all the officials. There is a short report by Sir Douglas Galton, a longer and more detailed report which is signed by Dr. Corfield, the honorary foreign secretary, and Dr. Poore, the honorary secretary general, who were also honorary secretaries to the Organising Committee. This report contains many statements which tend to show the magnitude of the Congress. For instance, we find the following which may be quoted.

As regards the numerical strength of the Congress, the following facts may prove of interest. First as regards the delegates, it will be found that 316 municipal, learned and philanthropic bodies in the British Islands appointed 636 delegates, 39 bodies in India and Ceylon appointed 67 delegates and 19 bodies in the British colonies appointed 27 delegates. This gives a total of 780 delegates, appointed by 364 bodies in the British Empire. In addition to this, 25 Governments and 197 municipal and other bodies in foreign countries appointed 352 delegates so that we have a total of 1132 delegates appointed by 586 Governments, corporate bodies and associations throughout the world. The numbers of the delegates appointed by various bodies in foreign countries were as follows: Governments and Government departments 144, cities, corporations, and provincial councils of health, 108, medical and other professional and scientific societies 73, universities, colleges and faculties of medicine, 65, hygienic societies, 40, and other bodies, 6. The same delegate was frequently appointed to represent more than one body. Many of those persons who were appointed delegates were unable, from various causes, to attend the Congress, but, on the other hand, a very large number of persons interested in hygiene and demography

it is also proposed to give a certain amount of clinical teaching and practical work to students at the Cardiff Infirmary, and to provide systematic courses of lectures in such advanced subjects as obstetric medicine and in medical jurisprudence, thus aiming at a complete medical education, both theoretical and clinical, and on a practical as well as on a merely scientific basis. The training is to be a thorough one, and the idea of the founders of the medical school is obviously to keep the student mainly, if not exclusively, in Cardiff. Early scientific education can be effectively and advantageously carried out in the provincial colleges, but a complete medical training in the practical branches of our art can only be obtained in the very largest centres of population. Clinical material of sufficient variety and clinical teachers of the first eminence can seldom be found together in provincial cities or towns, and even if the latter exist there they will always be under a temptation to move to larger areas. Medical science and art cannot be provincial without having the tendency to become unduly narrowed.

THE GENERAL COUNCIL OF THE EDINBURGH UNIVERSITY AND THE COMMISSIONERS' DRAFT FINANCIAL ORDINANCES

A SPECIAL MEETING of the General Council of the University of Edinburgh was held last week and was summoned mainly to receive and consider the report of the Committee on Ordinances, more especially on the draft financial ordinances issued by the Commission. The report deals, in the first place, with the proposed scheme, pointing out that it is intended that the class fees, instead of being paid to the professors directly, are to be paid to an official of the University Court and are to go to a fee fund. Each professor is to receive, firstly, the endowment on the Parliamentary grants attached to his chair and, secondly, a sum from the fee fund sufficient to bring up his salary to the "normal salary," which is fixed by the Commissioners in each case. The normal salaries are to vary from £500 to £1400 a year. This so-called "normal salary," the report points out, is really the maximum salary, as no provision is made for an increase beyond this. There is, on the other hand, provision that the emoluments from a chair shall not fall below what is called the "minimum salary." In so far as the salary may exceed the minimum rate, the only guarantee is the fee fund, and the "normal salary" can only be attained if the fee fund is able to meet all the calls made upon it. The report takes up, firstly, the fee fund, and cordially approves of the general principle underlying it, but the committee have had to consider whether the fees of students should be collected into a separate fee fund for each faculty or go into a common fund, and on this important point the committee does not come to a decision, considering it could hardly do so without more knowledge as to the provision the Commission proposes to make for the payment of lecturers &c. Taking up, then, the question of minimum salaries, the committee approves of the principle that a minimum salary be guaranteed, but it highly disapproves of a separate minimum for each chair. The reason for opposing this is that a professor's status is not affected by the subject he teaches or by the number of classes he teaches, neither ought his guaranteed minimum salary to vary with these conditions. A varying or graduated minimum seems wrong in principle. The minimum ought to be as high as the University can afford, but it ought to be the same for all. The committee considers that the irreducible minimum ought to be £500 a year. The proposal to which the committee object most emphatically in principle is that of a fixed maximum salary, called by the Ordinance a "normal salary." Quoting from the report by the University Commission of 1878, as follows: "It is desirable, if possible, to give every professor the incentive to exertion which the dependence of a portion of his income on the success of his teaching and the number of his students gives," the committee adhere to the principle expressed therein. The Commission, instead

of modifying or regulating the stimulus of material success as was desirable, has proposed to abolish it altogether, and the committee regard this as a serious and fatal mistake. The report says "As long as human nature is what it is, men, even learned men, will be incited to exertion by a regard for their own interests as well as by other legitimate motives. Scottish professors have not shown themselves to be more insensible to that influence in the past than other men." If this plan be adopted, "every professor will be invited to realise the fact that his most assiduous exertions and most brilliant efforts, though they may double the number of his students, will add nothing directly to his own income; and, on the other hand, that his income will suffer no appreciable diminution even after he has emptied his classroom by the latest reading of the dullest lectures." It is pointed out by the committee that the Senate have recommended that after receiving the minimum each professor should receive all his fees until a second fixed point is reached, after which he should receive one third of his fees, the remaining two-thirds going to the common fund. Another scheme that has been proposed is that after the minimum salary is paid the surplus should be divided into three parts—one to go to the professor, one to his faculty and one to the University. The committee does not commit itself to either of these, but it appears to think either of them better than that proposed by the Commission. As for the question as to whether or not there ought to be a superior limit and a maximum salary, the committee think that the maximum is determinable by consideration of the number of students a professor is competent to teach and to examine in each class, and that the University Court should be called upon to fix it in each case upon this principle. On the matter of vested interests the committee point out various faults in the Ordinance, and they hold that in all future appointments to chairs in medicine the University Court should have liberty to revise the conditions of each chair. The objections to the Ordinance are summarised as follows:—1 The proposal of separate minimum salaries for each chair cannot be justified in principle, whilst it would prove invidious in practice. 2 The withdrawal from the professors of all direct interest in the success of their classes is an unnecessary interference with the natural incentives to energy and enterprise. 3 The limitation of salaries to a rigid normal or maximum, differing for each chair, is an artificial arrangement, calling for a constant readjustment in the future to changing conditions, a readjustment which is not provided for. 4 The proposed relations of the different faculties in regard to the fee fund would interfere with harmonious working in the Senate and might lead to serious injustice.

The main amendments proposed are:—1 There should be a uniform minimum salary of £500 a year guaranteed to each chair. 2 Each professor should retain a certain interest in the fees paid for his class. 3 The upward limit of salary should be determined by decisions of the University Court fixing the extreme number of students to be taught in a single class.

The adoption of this report was moved by Mr TAILOR INNES, Advocate, and seconded by Mr SCOTT DALGLEISH, LL.D., and unanimously agreed to.

The report of the Finance Committee was then submitted. It criticises very severely the proposed financial arrangements by the Commission. It states that the committee doubt the wisdom of the Commissioners' plan of attempting to find salaries for the non medical chairs out of fees earned in the medical faculty. These fees, it is stated, are liable to violent fluctuations and it is suggested that the Commissioners have been induced too readily to draw for general purposes upon the medical fees in consequence of the attitude of the medical professors who represented to the Commissioners that additional chairs were not wanted in the medical faculty. How far this view is correct the report does not inquire, but it says that it is certain that a large body of non professional medical opinion is satisfied that greatly increased teaching power and appliances are absolutely necessary for the Medical School is to hold its own in competition with newer institutions. The report further states that the committee was favoured with a memorial which contains the fees for 1891-92, that the shrinkage there shown greatly exceeds the committee's estimate, and that the figures given by the Medical Faculty prove that without any further shrinkage in the current or future years the Commissioners' surplus of £8225 from the medical chairs has fallen below £2500. This report was also unanimously agreed to.

that of the best regulated private dwelling Preventive medicine, as applied to communities, could also claim to have gained by bacteriology as was last year shown clearly enough in connexion with the dreaded cholera Pasteurism could also claim to have already originated cures for some diseases, and the promise for the future was in this direction exceedingly rich Bacteriology had, moreover given us the knowledge not only of the minute organisms themselves as exciters of disease, but also of their action through the toxic substances they produced. In view of all this, would it be too much to describe Pasteur's first discoveries as epoch making and to give to him a place only second to Darwin in the history of the science of the past thirty years? "But it may be asked," Dr Grieve continued "what have we as practitioners specially to do with these matters which are apparently mainly questions of science? It is true that to very few of us is given the opportunity of developing into skilled bacteriologists, but it is open to us all to be to a greater or less extent skilled clinicians This being the case, it is possible to utilise the knowledge provided for us by the bacteriologist and in some cases, it is to be hoped to add to it. If the scientific laboratory is not at our command, the huge laboratory of nature is at all times carrying on its operations under our eyes, independently of our actions and after all it is in this laboratory that the facts of bacteriology, as facts in all branches of scientific medicine, must receive their final confirmation Now the local circumstances render the conditions under which these natural experiments are carried on more simple and more easily followed than they are in a European community Here the population is in great part sparsely scattered over a considerable space and lives under the most simple conditions The course of disease and its origin are therefore more easily traced than they are in huge collections of people with complex surroundings" "It was," said Dr Grieve, "with the hope of exciting a deeper interest in this study that the subject of this year's address had been chosen."

VICTORIÆ REGINÆ ET IMPERATRICI FLORENTIA

S P D

BRITANNA regum filia, sunt tibi
Flores et omnis copia narium,
Quoscumque de villis odores
Aura rapit zephyri jocosa,

Jamdudum apud me, Rumpe, precor, moras,
Caliginoso sub Jove frigidam
Urbem relinques et fruare
Delicias tibi destinatis

'Regina salve! grata redis!' sonat

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT

REPORTS OF MEDICAL OFFICERS OF HEALTH.

River Tyne Port Sanitary District—Dr Armstrong has issued a very complete report in reference to his district. It shows evidence of considerable vigilance and activity, and cholera certainly ought to find some difficulty in breaking through the Tyne defences. Owing to the delay arising from the medical officers, when examining ships, being carried far up the river above the boarding station, the Tyne Pilotage Commission gave orders that all vessels which required to be medically examined were to be slowed on passing the hailing station. Detention at the mooring station was only practised in the cases of vessels having possibly infected water ballast or bilge water, which it was necessary to pump out before docking. Dr Armstrong draws the attention of the authority to two sources of danger against which it is important to provide—viz, infected ballast and infected cargoes or holds. He states that "the means of dealing with ballast of infected fresh water or freshwater sand are not satisfactory, the appliances for disinfecting on a large scale are insufficient. During the year 1892 there were 1485 vessels boarded by the officers of the port sanitary authority on account of their having come directly or indirectly from foreign ports infected, or suspected to be infected, with cholera fever or small pox. Three masters of vessels gave false reports as to the health of persons on board. Emigrant vessels have been visited by the inspector on arrival and kept under supervision whilst in port. Some 9852 vessels, including 714 fishing boats, were inspected during the year. 151 structural defects were observed and 149 were remedied on notice. 1085 notices were issued to abate nuisances or remedy sanitary defects. In 524 cases the drinking water was ordered to be changed and the tanks to be thoroughly cleansed. As Dr Armstrong observes it is much to be regretted that port sanitary authorities possess no legal power to deal with provisions supplied to seamen which are unfit for food. The only way they can be dealt with is as nuisances under the Public Health Act. The addresses of 3079 persons were taken in accordance with the cholera regulations. Four seamen gave false addresses and were fined £10 each with an alternative of seven days imprisonment. Sea burial in the case of a corpse dead of cholera was not thought desirable owing to the shallowness of the North Sea and the possibility of the body being dredged up by the trawlers. 135 vessels with freshwater ballast taken in at infected ports were ordered to be pumped out and the bilges of all vessels from infected ports were

became members of the Congress on their own initiative. There were altogether 2483 full members of the Congress, of whom 1887 were inhabitants of Great Britain, 58 inhabitants of India and the colonies and 538 inhabitants of foreign countries. In addition to the 2483 full members of the Congress there were some 400 lady members and about 200 representatives of the press both British and foreign, to whom complimentary tickets were accorded. Thus, the total number of our guests during the Congress week exceeded 3000.

"The success of the Congress has been very largely due to the division of labour and the zeal with which each department was worked, but as the organisation of the parts became more perfect the work in the central office became steadily more arduous, until at last the mere labour of opening letters and ordering the correspondence occupied several hours daily. During the session of the Congress the paid and honorary staff amounted to more than 100 persons, and some idea of the work involved by the organisation may be gathered from the statement that 195,250 circulars, 110,310 programmes, and 20,000 invitation cards and programmes were disseminated, whilst the general correspondence took over 22,000 sheets of note paper and correspondence cards."

LOCAL CONTROL OVER DRAINAGE

WE had occasion in our issue of March 18th to comment upon a letter, which appeared in the *Builder* for Nov 5th, 1892, from Mr Arthur Baker, F.R.I.B.A., on the subject of the control exercised by local authorities over drainage and sanitary work. Since then we have received from Mr Baker a further communication, in which his views on the matter have been more fully laid before us. After dwelling upon the great advances that have been made in recent years in sanitary science, Mr Baker compares the actual progress we have made in practical house sanitation with the amount of knowledge we possess upon the subject, and is constrained to admit how great indeed is the difference between theory and practice. With respect to the generally insanitary condition of house property, Mr Baker quotes the opinions of two medical officers of health—one of a fashionable West-end parish and the other of a poorer district—in which the former states that he does not believe that a dozen houses could be found in any street in a satisfactory sanitary condition, and the latter that a dozen houses constructed according to the standard of modern sanitary science could not be found in the whole parish. Likewise to the point is the case instanced by the writer of a client who searched in vain for a house at the annual rental of £55 in which the drainage had been planned according to the most advanced ideas of sanitary engineers, and who, in despair, was in the end obliged to pay the money out of his own pocket to attain his ambitious ideal. In casting about for the reasons of these shortcomings Mr Baker eventually reduces them to two—(a) The defective provisions in the Public Health Acts relating to the qualifications of sanitary officers, (b) the absence of uniformity in the codes of bylaws adopted by local authorities.

In commenting upon the qualifications necessary for the post of medical officer of health, Mr Baker says "Of the value of the diploma as showing a complete knowledge of physics, chemistry, analysis of air and water, the laws of heat, pneumatics, hydrostatics, the disposal of sewage and statistical methods, I cannot pretend to judge, but as regards house drainage and sanitation, I venture to think that the test is neither sufficient nor satisfactory. In the examination by the Royal College of Physicians and Surgeons only three questions out of fifty-five, and those of the most elementary kind, relate to this subject, and in the Cambridge University examination I only find two questions out of twenty-seven." Our correspondent has also very little hope that the knowledge upon which such slight stress is placed by examining bodies can with any certainty be acquired by the six months' practical training with a medical officer of health, for he says "If the unfortunate candidate falls into the hands of such medical officers as I have known, who either think that a stinking drain is both natural and harmless or that a longhopper is a sanitary apparatus, or is ignorant of the danger to health likely to arise from the use of certain forms of grease traps, the syphonage of traps from want of proper ventilation of soil and waste pipes, and the imperfect execution of other

details, he will become a medium for the dissemination and perpetuation of sanitary heresy." Equally poor is the opinion entertained by Mr Baker of the knowledge of sanitary surveyors, for he believes that these officials may be and are most frequently appointed without any test of knowledge of house sanitation being imposed.

We venture to think that Mr Baker's views are somewhat pessimistic regarding the education of medical officers of health. The fact that the questions set at the written examination for the diplomas of Public Health held by the Royal Colleges of Surgeons and Physicians and the University of Cambridge, respectively, contain so few questions on house sanitation cannot be advanced as an argument in support of the contention of the slight importance in which the subject is held by the examiners. These tests consist not only of a written but also of a practical portion, and Mr Baker may rest assured that a subject of such first-rate importance in the future work of the candidates always receives its due share of attention at the hands of the examiners. We are also in a position to state that the subject of house drainage is one which is attended to with scrupulous care in the preparation of candidates for the public health diplomas and that practical demonstrations of apparatus and house drainage are repeatedly given to students. As regards the appointment of sanitary inspectors, any local authority not caring to insist upon a sanitary qualification would at present be quite within its rights, but on and after Jan 1st, 1895 it will be necessary for candidates appointed to such posts either to be the holders of a certificate granted by a body recognised by the Local Government Board or to have had three years' experience prior to 1895 in some London district with a population of not less than 20,000 inhabitants. Whilst we must insist that the tests which medical men are subjected to before a diploma in sanitary science can be obtained are sufficient, we cannot deny that the amount of house inspection personally carried out by the medical officers of health of London is far too small. The reasons for this are no doubt complex, but we believe that one of the chief reasons will be found in the fact that the medical officer of health is not required to devote the whole of his time to his sanitary duties. Indeed, the pitiful salaries so frequently offered by local authorities to their public health officials successfully prevent men from giving themselves completely up to the work, however inclined they may be to do so.

As regards uniformity in the codes of bylaws adopted by sanitary authorities, we do not see how this could be effected save by legislation. Could the adoption of the model bylaws of the Local Government Board, enlarged and extended, be enforced throughout the country, no doubt a great impetus would be given to house sanitation.

BRITISH GUIANA MEDICAL ASSOCIATION

THE quarterly general meeting of this Association was held on Jan 26th. Dr Robert Grieve, Surgeon General and President of the Association, was in the chair, and the members present were Messrs Wallbridge, Williams, Rowland (secretary), Gomes, Hill, von Winckler, Teixeira, Conyers, Rohlehr, Ozzard, Bonse, McAdam, Egan, Irving, Law, Castor and Bezbaron.

The chairman gave a satisfactory statement of the progress of the Society. The secretary read a communication from the British Institute of Preventive Medicine, asking for assistance towards the endowment of a central institution, after which the President delivered an interesting address on the Progress of Medicine during the present century. Sketching in an instructive manner the history of the growth and change of opinion with regard to the essential nature of pneumonia from the days of Cullen to the present time, and taking small pox as the type of specific disease, he dealt at greater length with the germ theory of disease, and paid an eloquent tribute to the services of Pasteur in this great and important field of scientific investigation. To Pasteur, he said, we owed the first practical idea of the production of disease by bacteria—an idea which in the hands of the distinguished writers who followed him had given us antiseptic surgery and all that had been rendered possible by its means. To this idea and its fructification was owing the conversion of maternity hospitals from places of entry into which placed the woman's life in imminent jeopardy into places whose salubrity equalled

were registered in Brighton, Leicester, Swansea and Huddersfield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 23·2 and 22·3 per 1000 in the preceding two weeks, further declined to 21·2 during the week ending March 18th, but exceeded by 1·3 per 1000 the mean rate during the same period in the thirty three large English towns. The rates in the eight Scotch towns ranged from 14·7 in Leith and 16·6 in Greenock to 23·5 in Glasgow and 27·5 in Dundee. The 597 deaths in these towns included 45 which were referred to measles, 6 to scarlet fever, 6 to diphtheria, 6 to whooping-cough, 5 to diarrhoea, 2 to small pox and 1 to "fever." In all, 71 deaths resulted from these principal zymotic diseases, against 91 and 95 in the preceding two weeks. These 71 deaths were equal to an annual rate of 2·5 per 1000, which exceeded by 0·4 the mean rate last week from the same diseases in the thirty three large English towns. The fatal cases of measles, which had been 53 and 49 in the preceding two weeks, further declined to 45 last week, of which 24 occurred in Glasgow, 11 in Dundee and 5 in Paisley. The deaths referred to diphtheria, which had declined in the preceding three weeks from 10 to 7, further fell to 6 last week, of which 5 were recorded in Glasgow. The 6 fatal cases of scarlet fever corresponded with the number in the previous week, and included 3 in Edinburgh and 3 in Leith. The deaths from whooping cough, which had been 15 and 17 in the preceding two weeks declined to 6 last week, of which 5 occurred in Glasgow, where the 2 fatal cases of small pox were also recorded. The deaths referred to diseases of the respiratory organs in these towns, which had been 171 and 142 in the preceding two weeks, further declined to 136 last week, and were 47 below the number recorded in the corresponding week of last year. The causes of 48, or more than 8·0 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin, which had been 27·7 and 25·2 per 1000 in the preceding two weeks, rose again to 26·0 during the week ending March 18th. During the past eleven weeks of the current quarter the death rate in the city has averaged 28·3 per 1000 the rate for the same period being 22·2 in London and 21·0 in Edinburgh. The 174 deaths in Dublin showed an increase of 5 upon the number in the preceding week, and included 4 which were referred to whooping cough, 3 to "fever," 2 to measles, 1 to scarlet fever 1 to diphtheria, 1 to diarrhoea, and not one to small pox. In all, 12 deaths resulted from these principal zymotic diseases, equal to an annual rate of 1·8 per 1000, the zymotic death rate during the same period being 2·3 in London and 1·6 in Edinburgh. The fatal cases of whooping-cough, which had been 5 and 1 in the preceding two weeks, rose again to 4 last week. The deaths referred to different forms of "fever," which had been 6 in each of the preceding two weeks, declined to 3 last week. The two fatal cases of measles exceeded the number recorded in any recent week. The 174 deaths registered in Dublin last week included 25 of infants under one year of age and 38 of persons aged upwards of sixty years, the deaths both of infants and of elderly persons considerably exceeded the numbers returned in the preceding week. Seven inquest cases and 6 deaths from violence were registered, and 63, or nearly a third, of the deaths occurred in public institutions. The causes of 6, or more than 3 per cent., of the deaths in the city last week were not certified.

CALCUTTA.

The Memorandum for the month of November last from the Health Officer Department Calcutta, is the first monthly report in which the vital statistics of the entire area of Calcutta are shown together, in accordance with the wishes of the Indian Government. The total number of births registered in Calcutta during November was 1294, giving an annual birth rate of 22·7 of the population. Of these 667 were males and 627 females. The total number of deaths (exclusive of still births) registered in Calcutta during November was 1868, against 1480 in the preceding month showing an annual death rate of 32·8, against 26·0 per 1000 of population. Of these 127 were from cholera, 232 from bowel complaints, 1 from small pox, 775 from fevers

28 from injuries, 79 from tetanus and 626 from all other causes. The proportion of male to female deaths was 148 to 100. In urban Calcutta the number of deaths was 1095 giving an annual ratio of 28·1 per 1000, of these deaths 80 were from cholera. In suburban Calcutta the number of deaths amounted to 772, giving an annual ratio of 43 per 1000. There were 47 deaths from cholera and 109 from bowel complaints.

THE SERVICES

MOVEMENTS IN THE MEDICAL STAFF

SURGEON CAPTAIN A. E. Morris will be transferred from Netley for general duty in the Southern district on the arrival there of Surgeon Lieutenant Colonel H. H. Stokes, A.M.S. Surgeon Captain W. R. D. Crooke has been appointed to the Coldstream Guards in place of Surgeon Captain J. F. Bateson. Surgeon Lieutenant Colonel Finlay, retired pay, has been appointed to Jersey, and Brigade-Surgeon Batho formerly at Jersey, to Guernsey. Surgeon Captains Burrows and Robinson have embarked for Egypt, and Surgeon-Captain Hickson for Malta. Surgeon Captain Geddes has been transferred to Devonport, Surgeon Captain Harris to Aldershot as Adjutant of the Medical Staff Corps and Surgeon-Lieutenant Read to Bristol. Surgeon Colonel Jameson has arrived in England from Egypt and taken over the duties of Professional Assistant to the Director General at headquarters in succession to Surgeon Major-General Reade, who retires.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon Captain Frederick Flood Moore to be Surgeon-Major (dated March 22nd, 1893)

INDIA AND THE INDIAN MEDICAL SERVICE.

The following appointments have been made—Surgeon-Major W. G. King M.B., to act as Superintendent, Lunatic Asylum, Madras during the employment of Surgeon Lieutenant-Colonel S. L. Dobie on other duty. Surgeon Major G. L. Walker M.D., is appointed to be Civil Surgeon, Ootacamund, in succession to Surgeon Major J. Maitland, M.D. Surgeon Major O. J. Bourke, A.M.S., in charge of Station Hospital, Kirkee, to the Medical Charge of Station Hospital, Purandhar, on expiration of Surgeon Captain H. J. Barnes', A.M.S., tour of duty there on March 23rd, 1893. Surgeon Lieutenant-Colonel T. C. H. Spencer, I.M.S. 7th Regiment Madras Infantry, to the Officiating Medical Charge of the Regiment. Surgeon Captain R. W. S. Lyons, M.D., to act, in addition to his own duties as Assistant Surgeon to the David Sassoon Hospital, Assistant to the Civil Surgeon, Poona, and Teacher of Surgery and Midwifery, Medical School, Poona, during the absence of Surgeon Captain W. H. Burke, M.B., on privilege leave. Surgeon Captain A. V. Anderson M.B., has been appointed to act as Deputy Sanitary Commissioner Central Registration district during the absence of Surgeon Major A. W. F. Street, D.S.O. The services of Surgeon Major F. F. MacCarte, M.B., B.Ch., have been placed at the disposal of the Government of India in the Department of Finance and Commerce. The services of Surgeon Captain J. C. Lamont, I.M.S., Bengal Establishment, are placed temporarily at the disposal of the Chief Commissioner of Assam. Surgeon Colonel P. S. Turnbull, I.M.S. having been appointed Surgeon General with the Government of Bombay, will proceed to Bombay to relieve Surgeon Major General J. Pinkerton, I.M.S. On his departure from Kurrachee, the Military duties of his office will, as a temporary measure, be carried on by Surgeon Lieutenant-Colonel W. D. Wilson, A.M.S. Surgeon Captain J. C. Culling, A.M.S. on return from sick leave in England, is posted to general duty, Bombay district. Brigade-Surgeon-Lieutenant Colonel A. S. Lethbridge, C.S.I., M.D., General Superintendent of Operations for the Suppression of Thugs and Dakaiti, has been nominated to be an Additional Member of the Council of the Governor General for the purpose of making Laws and Regulations. The undermentioned officer passed the examination in the Purvatya (Colloquial) language at Bakhlo on Jan. 20th 1893. Surgeon Lieutenant Colonel A. S. Reid, I.M.S. Leave has been granted to Surgeon Lieutenant Colonel J. D. Gunning, A.M.S. for six months or

disinfected with perchloride of mercury and pumped out before the ship entered dock. Commenting on the precautions for the future, Dr Armstrong writes "The safety of the entire population is jeopardised by every deficiency in preparation on the part of a port sanitary authority short of absolute perfection, and of every act of oversight or neglect, however small, on the part of any responsible port officer of health or inspector in performance of special cholera duties. The machinery and work for the prevention of cholera must therefore of necessity be as efficient and thorough in one port, irrespective of its size or the amount of its trade, as in another, otherwise the services of all the rest may be wrecked." In discussing our port defences, Dr Armstrong gives it as his opinion that "the best equipment of the kind in this country bears no comparison for completeness with that of the Louisiana State Board of Health at New Orleans."

Teignmouth Urban Sanitary District—The general death rate for the Teignmouth portion of this district during 1892 was 20.85, that for Shaldon 17.90. An analysis of the large number of deaths recorded in Teignmouth shows that the incidence during the first quarter of the year was much in excess of that in the remaining three quarters, and this fact seems to point to influenza as being the chief factor in producing this excess. The deaths from cancer were no less than 50 per cent. above the average, and this Dr Piggott is inclined to attribute, in great part at least, to the large proportion of aged persons amongst the inhabitants. The zymotic death rate was 0.44 per 1000. There were 19 cases of enteric fever notified in the district, 10 in Teignmouth, with a population of 6886, and 9 in Shaldon with one of only 1285. In Shaldon there are a large number of shallow wells, and we hope before long to hear of these being closed. The Notification Act is said to work very satisfactorily in the district, and the proceedings which follow upon notification seem to be very complete. Dr Piggott makes (what he calls) his "perennial complaint" as to the existing hospital accommodation. It seems that the only provision for the urban and port districts is of such a character "that the medical practitioners of the district have unanimously pledged themselves not to advise their patients to avail themselves of the indifferent accommodation provided." A local authority which, in face of an expression of an opinion such as this, fails to make proper provision must certainly be regarded as having neglected to fulfil one of the most important duties incumbent upon it. Furthermore it seems that the authority in question has recently deputed the officer who acts as an inspector of nuisances for both the port and urban districts to perform the duties of clerk of the works to a new sea wall in the course of erection. This is indeed taking a novel view of an inspector's functions, and we are glad to see that Dr Piggott speaks with no uncertain note as to the impropriety of the proceeding. As he states in his report, at a time such as this, when in view of the advent of cholera the inspector's unremitting attention should be given to improving the sanitary condition of the district, the authority has by its action practically decided to relax its efforts. A very interesting account of a recent limited outbreak of diarrhoea in the district is given in the report, and we hope to be able to give a short notice of it in a future issue.

Poole Urban and Port Sanitary Districts—The estimated population of this district in 1892 was 15,888 and it yielded during the year a general death rate of 20.70 and a zymotic death rate of 2.58 per 1000. The infantile mortality amounted to no less than 171 per 1000 births. An extensive and severe epidemic of measles occurred in the autumn which was accountable for 31 deaths. We notice that out of this number only 2 were in the cases of children under one year of age, so that this epidemic could not have greatly affected directly the high infantile mortality. Influenza caused 26 deaths. The Infectious Diseases Notification Act has just been adopted, and Dr Lawton again strongly urges his authority to revise the By-laws, which, it seems, are quite out of date. The report does not state what steps were taken with reference to the three samples of well water which were submitted for analysis and found to be impure. We are told that in five instances the disinfection of premises was carried out, but this seems a very small proportion of the large number of infectious cases which occurred. Plans for a new fever hospital were approved four years ago, but there the matter appears to rest. Acting as medical officer of health to the Poole sanitary authority, Dr Lawton very properly ordered the bilges and water casks of ten vessels which had come from a cholera infected littoral to be cleaned out previously to the ships being berthed. Some 77 inspections of vessels were

made by the medical officer of health and 157 by the assistant sanitary inspector. It would have been of interest had Dr Lawton given a short account of the port sanitary authority's equipment.

Sutton Coldfield Urban Sanitary District—This district is one of those in which measles has been added to the list of notifiable diseases, and, as Dr Bostock Hill remarks, the addition must be regarded rather in the light of an experiment. He is of opinion that the measure in a scattered district, largely rural, is a desirable one. There were during the year under review (1892) no less than 253 cases of measles notified amongst a population estimated at 8950. Of those attacked, as many as 80 per cent. were over five years of age, and, as Dr Whitelegge has shown that 90 per cent. of the mortality from measles occur in cases under five, this fact may to a large extent account for the death rate of the 253 cases being $\frac{1}{10}$. This high age incidence is explained by Dr Hill on the grounds that, the disease being notifiable, precautions are taken to prevent its spread, and as a result a somewhat large proportion of unprotected persons has accumulated. If the deduction can be justified by the facts, it is obviously a strong argument in favour of notification. There are, however, many complicated points involved in this question. The zymotic death rate of the district for 1892 was the lowest yet recorded, being 0.22 per 1000. The general death rate was but 13.4. Influenza, which prevailed in the district during 1891, seems then to have claimed all its victims, as it was practically absent during 1892. The infantile mortality was 130 per 1000 births, the chief cause of death being respiratory diseases and premature births. Great improvements appear to have taken place in the ventilation and flushing of sewers during the year.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty three of the largest English towns 6488 births and 3931 deaths were registered during the week ending March 18th. The annual rate of mortality in these towns, which had been 20.8 and 19.6 per 1000 in the preceding two weeks, rose again last week to 19.9. In London the rate was 19.1 per 1000, whilst it averaged 20.4 in the thirty two provincial towns. The lowest rates in these towns were 13.9 in Derby, 14.4 in Croydon, 15.3 in Leicester and 15.8 in West Ham, the highest rates were 23.7 in Preston, 25.0 in Norwich, 25.2 in Liverpool, 25.5 in Manchester, and 29.3 in Bolton. The 3931 deaths included 406 which were referred to the principal zymotic diseases, against 398 and 350 in the preceding two weeks, of these, 102 resulted from whooping cough, 91 from diphtheria, 85 from measles, 52 from scarlet fever, 45 from diarrhoea, 23 from "fever" (principally enteric) and 8 from small pox. No fatal case of any of these diseases occurred last week in Wolverhampton, in the other towns they caused the lowest death rates in Brighton, Derby, Halifax and Plymouth, and the highest rates in Preston, Cardiff, Manchester, Bolton and Croydon. The greatest mortality from measles occurred in Huddersfield, Hull, Leeds, Croydon and Bolton, from scarlet fever in Gateshead and Bolton, and from whooping cough in Burnley, Preston and Birmingham. The mortality from "fever" showed no marked excess in any of the large towns. The 91 deaths from diphtheria included 65 in London, 6 in Manchester, 5 in Cardiff and 3 in Birmingham. Three fatal cases of small pox were registered in London, 2 in West Ham and 1 each in Bristol, Liverpool and Oldham, 207 cases of this disease were under treatment in the Metropolitan Asylum Hospitals and 8 in the Highgate Small pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2065, against 2293, 2210 and 2147 on the preceding three Saturdays. 180 new cases were admitted during the week, against 208 and 195 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had declined from 427 to 351 in the preceding three weeks, further fell to 338 last week, and were as many as 208 below the corrected average. The causes of 62, or 1.6 per cent., of the deaths in the thirty three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Nottingham, Sunderland, Newcastle upon Tyne and in eight other smaller towns, the largest proportions of uncertified deaths

last week) is present in the urine during a course of years without other renal symptoms. The term "albuminorrhœa" has been proposed to denote these cases. They are, I believe, notwithstanding the statements recently made, not common, and their comparative rarity has hindered the growth of accurate knowledge concerning them. When the cases belonging to other classes have been sifted out it will be found that few observers are familiar with more than one or two of the class alluded to, and hence their impressions are necessarily derived from too small a field of observation. Here the record and careful analysis of a number of cases could hardly fail to lead to conclusions of value. In such cases we need above all the guidance of necropsies, and these are very seldom obtained. It has appeared to me not improbable that mechanical conditions, sometimes congenital, affecting one kidney or part of one kidney, may account for some of these cases. Mr Henry Lee¹ once made a very suggestive post-mortem examination of the body of a man who had long had albuminuria without apparent cause. He found intussusception of one ureter. Another class of cases has been well described by Dr Clement Dukes—temporary albuminuria, with headache, syncope and high vascular tension occurring in the period of youth—but these I think are on the border line of the present inquiry. There would seem to be inflammatory hyperæmia of the kidney in such cases. A further considerable class of cases which is of much importance to the life assurance examiner is that of temporary albuminuria from accidental causes such as shock to the surface in bathing, severe muscular exercise or ingestion of albuminous food—typical "physiological albuminuria," to use the phrase of Sir W. Roberts. Yet another class might be added—spurious albuminuria, in which the albumen is derived from other parts of the urinary system than the kidney, catarrh of the renal pelvis or ureter or of the bladder produces such a result. Slight gleet in young men vitiates our tests in not a few life assurance cases, and, lastly, as hinted by Dr Routh, leucorrhœa is, in women, an exceedingly common cause of spurious albuminuria. Dr Vagure and others have laid much stress upon the connection between albuminuria and conditions of vascular tension and have advanced the view that, in most of the cases alluded to, the causes operated by means of alterations of the blood tension. There can be no doubt that the tension of the vessels is a factor of great moment in many of these cases and that there is a true albuminuria of low tension² as well as "albuminuria of high tension." But added experience has convinced me that there are other factors at work in many cases and that vascular tension will not explain nearly all the instances met with.

One word with regard to statistics of albuminuria. Dr Lauder Brunton is reported to have drawn, at the meeting of the Medical Society, a comparison between the proportion of albuminuria cases found amongst healthy men by himself in England (2 per cent) and by observers in America (9 per cent) respectively and to have inferred from these statistics the greater prevalence of albuminuria in the latter country. But are not such statistics absolutely useless for comparison, since they depend entirely on the methods of the observer? I have myself stated elsewhere² the results of the examination of 282 presumably healthy adults for life assurance, amongst whom I found eighty six, or 30 per cent., to show traces of albumen in their urine. No two observers will exactly coincide in their appreciation of a "trace" of albumen—that which one disregards, another, with finer methods, will enter as albuminoids. What then should be the scope of the inquiry which you, Sirs, have proposed? I take its subject to be 'albuminuria unattended by other evidence of kidney disease.' Records of cases especially such as cover a series of years, should be collected. To what sources can we look for such records? I think with Dr Tyson that it would be very difficult to make much use of the records of insurance offices. Their medical reports are commonly too brief for this purpose, and to be of use the observations almost need to be made with this special end in view. It is from the case-books of medical men, themselves interested in this subject, that material must be obtained—the notes of the cases of persons in the middle and upper ranks of society who have been watched for years by their physicians. The records of necropsies should especially be coveted. What should be our aims in collecting and analysing these records? To place the

cases in clinical groups so far as these can be defined. To do this one has to take account of all associated or pre-existing conditions, especially of vascular tension and blood conditions, and of inherited or associated diathesis. It would not be difficult to sketch out a schedule for the description of these cases. Cyclic albuminuria is so common that a few well chosen cases should suffice to represent this class, those in particular which extend over a good many years. Cases of permanent albuminuria without apparent cause should be stated in more fulness.

Lastly, there are two features in the records which would require especial attention. One is the kind of albumen present—whether globulin, propeptone or any other modification formed a part or the whole of it, where possible the tests employed should be stated. The other feature is the after history—whether progressive renal disorder eventually supervened. Conducted on some such lines as these, I cannot but think that the inquiry would prove of much service, and that it might supply us with solid groundwork for the prognosis of these difficult cases.

I am, Sirs, yours truly,

Finsbury-square March 11th, 1893.

R. HINGSTON FOX.

THE TREATMENT OF HÆMORRHOIDS AND PROLAPSE OF THE RECTUM BY CLAMP AND CAUTERY

To the Editors of THE LANCET

SIRS.—Mr Henry Smith's article, published in THE LANCET of March 4th on the above subject, might lead one to imagine that the operation by the clamp and cautery possessed every possible advantage. With all due deference to such an authority I think it only right to recall to the minds of the readers of THE LANCET the disadvantages of this mode of treatment. It is at least four times as fatal as any other method of removing hæmorrhoids. The pain is as great as, if not greater than, that proceeding from other modes¹ for one should be well aware that in the rectum as in other parts of the body, a burn is one of the most painful of all injuries, similarly, contraction another usual sequela of burning, is by no means absent after the clamp and cautery procedure. Again, secondary hæmorrhage is likely to occur on the separation of the sloughs caused by burning. No doubt this operation may be suitable in selected instances, but to apply it to all cases of hæmorrhoids runs too near to the Procrustes' bed method of procedure to deserve much commendation at this period of surgery. It has been my lot to operate upon cases of hæmorrhoids in which the clamp and cautery had been used several years before. I treated them by crushing or by ligature, and was assured by the patients that the pain and after trouble were far less than they had suffered after the burning operation. Tetanus, pyæmia, secondary hæmorrhage and so forth are almost unknown now, and in his reference to them Mr Smith must be thinking of the era when the clamp and cautery were extensively used.

I am, Sirs, yours truly,

HERBERT ALLINGHAM, F.R.C.S. Eng

Grosvenor square W March 22nd, 1893.

"DENTAL ADVERTISING"

To the Editors of THE LANCET

SIRS.—Your correspondent 'A Looker On' thinks the agitation against dental advertising injudicious because it cannot possibly bear fruit. I hope it will bear good fruit. It is already awakening a great many to the disgrace of it and the degrading influence it has upon the whole dental profession. I trust this feeling will penetrate into the medical profession generally and through it into the public mind, and a man who makes a trade of an honourable profession—who seeks to emulate the proprietors of a soap or a mustard—will be scouted by all. It is true the General Medical Council admitted many advertisers to the Dentists' Register, but by so doing the General Medical Council did not make itself a party to advertising or sanction any vested interest in it, as your correspondent suggests. On the contrary, the General Medical Council have now a power over them they did not before possess. The Master of the Rolls and Lord Justices Lopes and Fry sitting as a court of appeal in the Partridge v. General Medical Council case, held that advertising was disgraceful conduct in a professional respect, and 'if there were evidence of it the decision of the Council is final and

medical certificate and to Surgeon Captain R. C. Thacker, A M S., to England for five months on private affairs. The undermentioned officers are granted furlough out of India: Surgeon Lieutenant-Colonel W. F. Johnson, M D., I M S., Queen's Own Sappers and Miners (u p a) for six months, and Surgeon Major E. S. Brander, Civil Surgeon Etawah on private affairs for eighteen months (from March 25th, 1893).

NAVAL MEDICAL SERVICE.

The following appointments are announced—Staff Surgeons: Everard H. Saunders to the *Colossus* and Alexander M. French to the *Boscawen* (dated March 22nd, 1893). Surgeons: Charles F. Warren to the *Seafarer*, Edward M. Dobinson to the *Martin*, Edgar F. Mortimer to the *Nautilus*, William E. Marshall to the *Pilot*, and Henry B. Hall to the *Liberty*. Surgeon and Agent: James C. Harkin, M B., to Teelin and Malinmore (dated March 16th, 1893).

YEOMANRY CAVALRY

Yorkshire Dragoons: Percy Barnard Mackay, Gent., to be Surgeon Lieutenant (dated March 18th, 1893).

VOLUNTEER CORPS.

Rifle: 1st Volunteer Battalion, the Lincolnshire Regiment: Surgeon Captain H. Wright to be Surgeon Major (dated March 18th, 1893).—3rd Volunteer Battalion, the Lancashire Fusiliers: John Furvill Smith, Gent., to be Surgeon Lieutenant (dated March 18th, 1893).—1st Nottinghamshire (Robin Hood): William John Sprott, M D., to be Surgeon-Lieutenant (dated March 18th, 1893).—2nd Volunteer Battalion, the Duke of Edinburgh's (Wiltshire Regiment): Surgeon Lieutenant F. F. Jones resigns his commission (dated March 18th, 1893).

THE VOLUNTEER OFFICERS' DECORATION

A further list of those officers upon whom this decoration has been conferred appears in the *London Gazette* of March 17th, 1893. Amongst them are the following members of the medical profession—*North Western District*:—*Artillery*: 1st Cheshire and Carnarvonshire, Surgeon Major William Bell.—*Rifle*: 1st Volunteer Battalion, the Prince of Wales's Volunteers (South Lancashire Regiment), Surgeon and Honorary Surgeon Major John Webb Watkins, retired.—*Eastern District*:—*Artillery*: 1st Essex (Eastern Division, Royal Artillery), Surgeon Major (ranking as Lieutenant Colonel) Rea Corbet, retired, 4th (Cambridge University) Volunteer Battalion, the Suffolk Regiment, Surgeon Major (ranking as Lieutenant-Colonel) Bushell Annington, retired.—*Home District*:—*Rifle*: 2nd Volunteer Battalion, the Duke of Cambridge's Own (Middlesex Regiment): Surgeon Lieutenant-Colonel Charles Arthur Patten, 1st Tower Hamlets (the Tower Hamlets Rifle Volunteer Brigade), Surgeon and Honorary Surgeon Major Thomas Gray, M D., retired.

THE SURGICAL CONGRESS AT PARIS

The British Army will be professionally represented at the Surgical Congress which will open at Paris on April 3rd by Brigade-Surgeon Lieutenant-Colonel Stevenson, Professor of Military Surgery at the Army Medical School, Netley.

A MEDICAL HERO

According to our contemporary, the *Indian Medical Record*, Surgeon Major Lloyd appears to have distinguished himself in the late attack on Sima by the Kachins. The garrison consisted of 275 men of the Military Police battalion. The Kachins who had taken up a strong position, opened fire and attacked the stockade. Surgeon Major Lloyd, at the request of the officer in command (Captain Morton), took charge of the upper angle. The latter officer was fatally wounded in the abdomen and Surgeon Major Lloyd advanced to his rescue. There was a heavy fire from a large force of the enemy, but all the Kachins were driven from the immediate vicinity of the stockade by Surgeon Major Lloyd and a strong party. This officer had previously served on the West Coast of Africa and had also seen much fighting in Boerland. He is said to be an excellent horseman and has the Zulu medal for South Africa.

THE WOUNDS CAUSED BY THE MANNLICHER RIFLE

According to the reports which have appeared in several papers the wounds discovered in the person of a soldier accidentally killed in the vicinity of the Vienna Arsenal by a bullet from a Mannlicher rifle are said to have thrown a new light on the effects produced by that weapon. A post mortem examination of the body showed that the bullet in this instance had acted almost as if it were an explosive in the

extensive nature of the injuries it had inflicted. But neither the exact nature of the injuries nor the structures injured are stated. Moreover, the projectile itself, owing to some flaw in its manufacture, was quite different to a small bore bullet. The steel covering had broken off from its leaden core, and the two portions of the bullet are stated to have made separate and independent channels, which together formed an absolutely fatal wound, and the rifle had been fired at a very short range, when, according to the observations of some experimenters, these bullets seem to act almost as explosives. The results of experiments with small bore bullets fired from rifles of this nature vary according to differences in the structure, strength and resistant powers of the parts struck, and, it is alleged by some, according to the ranges also at which the bullets are fired. From 50 to 200 yards the effect is said by some observers to be pulverizing and destructive. According to the observations of a Chilean officer, who published as his graduation thesis a study of the wounds inflicted by the Mannlicher bullet, when the shaft of a long bone is hit at a short distance, the effects may be described as explosive. Surgeon Captain Perry Marsh, as the result of his collection of the reports of cases of wounds inflicted with the Lee Mitford missile at various ranges—from 3 yards to 3000—says, however, that there is no evidence of any extensive disorganisation of the parts unless considerable resistance had been offered to the passage of the missile by a large compact bone. A projectile moving with high velocity might give rise to much disruptive violence at the point of impact with a resisting structure, and it is probable that a bullet projected with high initial velocity from the muzzle of a Mannlicher rifle does not at once acquire its steady rotatory drilling motion, so that a shattering effect might take place at short ranges which would not ensue at longer ranges.

Correspondence.

"Audi alteram partem."

THE PROGNOSIS OF ALBUMINURIA.

To the Editors of THE LANCET

SIRS.—The recent discussion on Dr Ralfe's paper before the Medical Society and the leading article of THE LANCET of March 4th have drawn fresh attention to this vexed question, one which comes every week before the medical officers of life assurance companies and often enough before practitioners in every walk of medicine. It cannot be denied that medical opinion on the prognosis of albuminuria is in an unsettled condition, and I write to support your suggestion that the Medical Society should appoint a committee to consider and report upon it. In order, however, to do this usefully one must entertain clear ideas of the objects of the inquiry and of its limits. The whole subject of albuminuria in general is far too wide for handling in this manner. It is, in the first place, albuminuria unattended by other signs of kidney disease that has to be considered. When the kidney is affected by inflammatory or degenerative change, whether acute or chronic, temporary or permanent, such change being indicated by other signs besides the presence of albumen in the urine, the condition is outside the scope of inquiry. Medical science is already in possession of sufficient facts on these heads to form the basis of definite conclusions. It is otherwise with cases of uncomplicated and unexplained albuminuria. Facts, well analysed and digested, are here greatly needed. There are probably many conditions underlying albuminuria in these cases. Certain classes of cases have been pretty clearly defined already, although I cannot follow Dr Ralfe in regarding the whole group of "functional albuminuria" as well defined. Dr Pavy, Dr Broadbent and others have described the condition known variously as cyclic, postural, or intermittent albuminuria, so that it is quite easy of recognition in typical cases, both in the mode of occurrence of the albumen and in the circulatory conditions which attend it. And typical cases are not at all uncommon in practice. A similar definition is needed for other forms of albuminuria, to be attained by the grouping together of cases which have clinical features in common. The class of cases which seem especially to need inquiry consists of those in which albumen in a measurable quantity (unlike the "very small trace" of Professor Gairdner's case

beneficial I may here say that from the results I have obtained in early phthisis from calomel vapour inhalations I believe they will yet be recognised as a most valuable aid in the treatment of this formidable disease. I should be very pleased if some of your readers who have an opportunity of observing the diseases that occur amongst those who work in mercury would say in what proportion phthisis occurs amongst that class of operatives, also if they find an immunity from typhoid fever amongst them.

"ISOLATION" & "INUCTION"

To the Editors of THE LANCET

SIRs.—Mr Curgenvin has been misinformed as to the action of the Enfield Local Board. He says that "in 1891 the Enfield Board proposed to build a hospital. They were advised to try the inunction method of disinfection first. They did so, and the hospital is not yet built." In December, 1891, a temporary hospital was not only proposed to be built but actually erected, and some 120 cases have been admitted up to the present time, although eucalyptus has been freely distributed at infected houses, and has been applied thoroughly to the patients admitted. The local board was never advised to try the inunction method first, and the delay in the erection of the permanent hospital on another site, which has been purchased, has had nothing whatever to do with the inunction of eucalyptus. The plans are now prepared and a loan is about to be applied for to build. I have no doubt that eucalyptus is a disinfectant, but I am equally sure that it cannot be relied on in place of isolation.

Enfield March 20th 1893 J J RIDGE.

LIVERPOOL

(FROM OUR OWN CORRESPONDENT)

The Assizes

IN his charge to the grand jury at the opening of the assizes here on the 14th inst. Mr Justice Wills laid great stress on the value of the medical evidence in two of the three cases of murder. In one it would go very far to reduce the crime to manslaughter, in the second it went far to show that the crime was really manslaughter and not murder, whilst in the third it would go very far to prove or disprove the statement made by the prisoner. The mate of a ship was tried for stabbing the captain whilst the vessel was on her voyage. There was no provocation whatever, the captain having merely desired the prisoner to keep on deck during his watch. The judge dwelt upon the danger of using a knife under such circumstances, far away from medical aid. It was aggravated by the fact that had the captain died the prisoner would, under ordinary circumstances, have taken the command. He sentenced the prisoner to seven years penal servitude.

Port Sanitary Work during the Year 1892

The report of the medical officer of health with reference to the work done last year to safeguard the health of the port against the importation of disease by vessels arriving in the river has been printed and is a very interesting document. Very effective measures were taken to prevent the entry of any cases of cholera during its prevalence in Hamburg. Two additional medical inspectors were temporarily appointed, in accordance with the order of the Local Government Board of Sept 6th, to visit all ships arriving in the Mersey from Hamburg and other cholera infected ports. These duties were performed by Drs Roberts and Imbach until the necessity for them ceased to arise. The number of vessels inspected during the entire year was 3867, whereof 2921 were British. The number found to be in good or fair condition was 3399, whilst 468 were defective in regard to sanitary requirements, the principal offenders as regards cleanliness being as in previous years, steamers carrying cattle. With the exception of these the condition of the British ships is reported to have been very satisfactory. Vessels of other nationalities have improved, especially the Dutch. Twenty five Spanish ships were fumigated and cleansed and certificates given by the medical officer, in accordance with the requirements of the

Spanish Government. The number of emigrants passing through Liverpool during the year was 200,786, being 5632 less than in the previous twelve months. This reduction is more than accounted for by the great falling off in the number of passengers to the United States, owing to the cholera scare, from 170,210 in 1891 to 157,212 in 1892. The report contains particulars in diary form of every case of sickness on board ship and amongst emigrants on arrival in Liverpool, with details of treatment.

The Resident Medical Officers of the Liverpool Workhouse and their Accommodation

Drs. Robertson and Alexander, the visiting physician and surgeon to the Liverpool Workhouse, having noticed the frequent breakdown in the health of their resident medical officers, have called the attention of the workhouse committee to the insanitary condition of the quarters allotted to the resident staff. These are in the centre of the building close to the wards. The chairman and another member of the committee admitted the existence of the insanitary condition and a subcommittee was appointed to inquire into the subject and to report to the committee.

The Health of Liverpool

At the last meeting of the health committee, held on the 16th inst. it was stated that the deaths for the week were 83 below the average of the past ten years. Under the Infectious Disease Notification Act were reported 40 cases of scarlet fever, 19 removed to hospital, 15 of 'fever,' 7 removed to hospital, 2 of diphtheria, not removed, 5 of small pox, all removed to hospital, and other cases. Patients under treatment in hospital for the week ending the 16th inst were—typhus fever, 9, typhoid fever 36, scarlet fever, 116, diphtheria 1, small pox, 15, chicken pox, 5. So far small pox has not made any serious advance. The weather has been very variable.

March 20th.

NORTHERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENT)

Newcastle Surgical Aid Society

THE report submitted to the annual meeting of the Newcastle Surgical Aid Society shows a falling off in subscriptions during the past year. It is the same all round with our charitable institutions, and this is to be accounted for by trade depression.

Small-pox in the North

One still hears of cases here and there over the northern counties. Cases are reported from Hexham, Durham City, Jarrow, &c. It is the same story, the disease is disseminated by vagrants and tramps, and there seems to be a good deal of difficulty in getting this class isolated and so stamping out the disease.

Cumberland and Westmoreland Convalescent Institution

The annual meeting of the Cumberland and Westmoreland Convalescent Institution was held at Carlisle last week, when the Bishop of Carlisle presided. It was stated that 623 patients had been admitted. Of these 239 were from Carlisle, 207 from other parts of Cumberland, 62 from Carlisle Infirmary, 53 from Westmoreland, 33 from Northumberland and 13 from other parts of England, with 16 from Scotland. The financial statement was on the whole more satisfactory than is usual with similar institutions as regards the past year.

Sunderland Provident Dispensary

The Sunderland Provident Dispensary cannot be classed with the so-called "Provident" ventures started to provide for its originators. It was shown in the last report that nearly 22,000 prescriptions had been dispensed, over £500 had been paid to the medical staff, and the year closed with a good balance in hand.

Death of a Newcastle Certenarian

Mrs Kate O'Hara died at Newcastle last week (in a district not distinguished for its sanitary perfections) in her 106th year. It appears that this is a genuine case as she was returned as 103 in the last Census. She was also entertained by the Mayor at that time.

Death of Dr Candlish, late of Alnwick

The news of the death of Dr Candlish, late of Alnwick was received with great regret. Dr Candlish died at Ayr last week, to which place he retired about two years ago after

conclusive They are the sole judges "1 Dentists can appeal to the courts it may be, so can the medical profession But the courts do not approve of barristers or solicitors advertising, and the courts would like to see "the dental profession in the same high position as other medical men "2 The Incorporated Law Society has converted the legal profession into an honourable condition It is for the General Medical Council to take the dental in hand and assist us, as it has been doing lately, to weed out the advertisers

HENRY BLANDY

"HOW UNION APPOINTMENTS ARE MADE"

To the Editors of THE LANCET

SIRS,—“M R C P” complains that union appointments are generally given to the man who buys the practice, and I venture to think ninety nine men out of every hundred would say, “and rightly so too” With your permission, I will ask “M R C P” this question Suppose, for argument's sake, he buys a village practice and I obtain the union appointment which had always belonged to that practice and worth, say, from £50 to £60 a year, and the work scattered over six or seven or more parishes, could I live and keep a horse on my appointment? If not, what follows? I must, to obtain the merest bread and cheese existence, be constantly poaching on the practice he has bought. What it may be in very large towns or cities I am not prepared to say, but in a village practice it would be impossible to do without the appointments such as union and clubs, and badly as we are remunerated for this work, they help to form an important total The amounts, though small, are paid regularly, and we know when to expect them, which is not the case with private patients Under these circumstances an opposition doctor in a village practice would be not only a farce, but the profession must in various ways be degraded thereby, and one of the two must inevitably come to grief. How would “M R C P,” after purchasing the practice, like to be the victim? Besides, I think it is mean and unprofessional in any man to oppose another after he has invested his small capital—perhaps all he has—in one of these practices From “M R C P's” style of argument it seems to me that the election was right when he was elected, but wrong when he was not

CANCER PLASTERS

To the Editors of THE LANCET

SIRS,—An inquest was lately held at Chester 10 Street which throws a strong light on the unsatisfactory state of the existing laws with regard to “quacks” A woman aged fifty, in spite of medical advice, went to a “cancer curer,” living close to Durham, who for a consideration of 15s for the first visit and 5s for each subsequent one applied plasters to a scirrhus of the breast about the size of a “small hen's egg” The “treatment” was continued at the rate of a plaster a week from the end of September, 1892, till death on Feb 13th, 1893 The surgeon, who had originally advised operation, stated at the inquest that (although all operative treatment was refused and the persistent use of the plasters against his urgent advice made him decline to attend the case further) he thought it probable that the woman would have lived for about another two years had not death been “accelerated by the application of caustic plasters” Pressed by the coroner as to the composition of the plasters, with considerable hesitation the woman stated that they were made of “the herbs wood betony, crow's toe and yarrow,” dried, powdered, mixed with white of egg and spread upon bladder skin She swore that no corrosive or other drug was used. After an hour's deliberation the jury returned a verdict “that deceased died from a cancer in her left breast,” declining to express any further opinion After the medical evidence one must regard such a verdict with great dissatisfaction Within the last few months three cases of such treatment have come under my notice, two of them the result of the same woman's handiwork.

Case 1—A domestic servant aged twenty nine applied to the above woman for what from the history was a small

warty growth on the dorsum of the right hand, about the centre of the metacarpal bone of the little finger She was told that it was a “shell cancer,” and that after a series of plasters it would drop off. Some ivy plasters were applied. When I saw her there was a large, foul, dark coloured oval slough over the above position, filling up an ulcer measuring one inch and a half by three-quarters of an inch. The sheaths of the tendons were eaten through, the metacarpal bone was eroded and the metacarpo phalangeal joint opened up, necessitating amputation of the little finger with a large portion of its metacarpal The wound rapidly healed and she is now at her duties The ulcer showed every sign of a corrosive action, and neither slough nor portions of skin removed showed any signs of malignant growth

Case 2—A joiner aged fifty nine presented himself with epithelioma of the lip and the angle of the mouth Five years ago he burnt his lip with a clay pipe, which left a small sore, which grew harder and never healed For the last ten months he had been under the same woman and had numbers of plasters The growth extended from almost the centre of the lower lip backwards to the left angle of the mouth, it then ran backwards for about one inch into the cheek, where there was a mass of epithelioma the size of half a walnut. Its removal (there were no enlarged glands) necessitated a very extensive loss of tissue, resulting in considerable deformity The cheek healed well, but when seen in January there were signs of recurrence on the lip

Case 3—A miner aged fifty about three years ago noticed a “marble” under the skin of the left thigh just above the patella. About two months before being seen he noticed that the lump was growing rapidly He consulted a man who professed to cure cancers, and who gave him a bottle of liniment to use and “punched” the tumour to try and “burst it.” Fortunately he did not succeed, for an encapsuled sarcoma, hemorrhagic, the size of a child's head, was removed, together with a large portion of skin implicated from just above the left knee The tumour had no deep connections, and the large raw surface left after so large a removal of skin slowly granulated up I have no doubt, from the appearance presented by the first two cases, that the plasters contained some powerful corrosive The nature of the herbs mentioned I do not know I think if all such cases were reported it might lead to some more stringent regulations being adopted

SELBY W PLUMMER, M B, B S

"SOME REMARKS ON THE PATHOLOGY AND TREATMENT OF TYPHOID FEVER"

To the Editors of THE LANCET

SIRS,—It was with considerable interest and pleasure that I read Dr Latham's remarks on the pathology and treatment of typhoid fever During the past seventeen years I have used calomel in the treatment of every case of the disease that came under my care, and always with the same results. I found it to lower the temperature, clean the tongue and brighten the patient, and in a large number of cases occurring in healthy subjects, and recognised early, the treatment was followed by a complete abortion of the disease. Being a general practitioner, the cases I have treated came early under my observation—that is, within the first ten days—consequently the mischief had not taken deep hold of the glandular structures of the bowel Calomel may not possibly have acted so impressively had this been otherwise. It is obvious that the main influence of the drug is in its germicidal and antiseptic properties Let I have been much impressed with the idea that much of its beneficial influence rests on the effect it has in relieving portal congestion, which is always present, producing a condition of turgescence in the immediate neighbourhood of the glandular mischief that much intensifies the disease. I have also observed that after the first few doses of calomel my patients passed much larger quantities of urine, which, no doubt, relieved the system of poisonous results I have never ventured to give larger doses than two grains, generally one grain and a half, three times daily, either alone or combined with compound ipecacuanha powder or opium, according to the frequency of the purgation My fear of larger quantities has rested on a dread of increasing the peristaltic action of the bowel, thus preventing that rest which I recognise as necessary wherever inflammation is present. I have also found the counter irritant effect of a large mustard plaster over the abdomen on first recognising the disease as very

1 See report in the Journal of the British Dental Association, vol xiii, p 225 April, 1892

2 Master of the Rolls Ibid.

natural ice consumed in Paris. The *Médecine Moderne* informs its readers that a sewer opens at the top of that sheet of water and that, besides, it is fed by an artificial stream, which, rising in the plateau of Gravelle, crosses a large part of the Vincennes wood. A visit to that wood on a fine Sunday will easily enable the observant sanitarian to judge of the manner in which the waters of this artificial river are adulterated by the numerous holiday makers strolling on its banks. Until provisions are made by the authorities to safeguard the purity of the natural product I should strongly recommend visitors to this city who indulge in the consumption of ice to insist upon being supplied with that manufactured artificially by the companies above mentioned.

The Petroleum Treatment of Diphtheria

In the third number of the *Normandie Médicale* Dr Flahaut relates the history of an epidemic of diphtheria that occurred at La Neuville—Champ-d'Oisel—in 1891-92, seventy persons being attacked. In the first and earlier series of cases (thirty) reported the usual topical treatment (carbolic acid, sublimate, salicylic acid &c.) was followed, with the result that nine out of the thirty patients died. For the remaining forty, local applications of petroleum were employed, all the cases recovering. From the day on which this new treatment was instituted the mortality became suddenly nil. M. Flahaut says—"I commenced this mode of treatment on a little girl whose fauces, tonsils and soft palate were covered with thick false membranes. From the very first applications of the petroleum the membranes were seen to whiten, retract and almost dissolve under the brush. The same evening she breathed more easily and expelled some membranous exudations. Five days later the child was, if not absolutely cured, out of danger, and complete recovery was only a question of time. From that time forth I employed petroleum locally in all my cases and I congratulate myself on having done so, since they all recovered." A throat brush dipped into the petroleum and shaken free of any excess of the liquid is passed every hour or every two hours, according to the gravity of the case, over the parts covered by membrane. The application is said not to be painful—on the contrary, it produces a soothing effect. The only drawbacks are the disagreeable taste and odour of the petroleum. Membranes expelled by patients and received into capsules containing petroleum are almost totally dissolved after a gradual process of disintegration. The treatment lasted on an average a fortnight, at the end of which recovery generally occurred almost suddenly. The diagnosis was confirmed by the discovery of the Klebs Loeffler bacillus and by the supravivention in several instances of complications and sequelæ, such as bronchitis, broncho pneumonia, paralysis and albuminuria.

The Orchilococcus

It has hitherto been taken for granted that the occurrence of orchitis—or rather epididymitis—in the course of an attack of gonorrhœa was due to the invasion of that organ by the migration of the gonococcus of Neisser. MM Hougoung and Eraud (Académie des Sciences, Feb 27th) appear, however, to have successfully isolated the specific microbe of blennorrhagic epididymitis. The newly discovered micro-organism is a diplococcus of much the same shape as Neisser's gonococcus, but it is larger, the isolated cocci measuring about 1 μ . Like the gonococcus, it is discoloured by Gram's method, but it is distinguishable from it by the following properties whilst the gonococcus is with difficulty cultivated even on human serum, in which it dies at the end of two or three days, the orchilococcus thrives well on peptone, peptonised gelatine, ordinary bouillon and alkaline solutions of casein and nuclein, maintaining in these different media the faculty of reproduction and the integrity of its forms for a year and longer. The orchilococcus is frequently found in gonorrhœal pus during the first few days of the disease. It happens, however, sometimes that this pus sown upon gelatine yields no culture. Now, when this is the case, such patients are never attacked with orchitis. If, on the contrary, pus thus grown on gelatine yields colonies of the micro-organism the onset of the testicular complication is to be feared. Negative cultivation results enable us therefore to foretell that the gonorrhœa will run its course without the epididymis being infected. The microbe exercises no action on the conjunctiva, the areolar tissue, the peritoneum, or on the urethra itself. On introducing the culture (on peptonised bouillon) into the testis of the dog, an attack of orchitis is induced. The inflammatory products collected from the bouillon culture produce the same effects,

but act much more energetically, the orchitis induced being often accompanied by profuse suppuration and being sometimes followed by atrophy of the affected organ.

March 21st.

BERLIN

(FROM OUR OWN CORRESPONDENT)

The Balneological Society

THE discussions of the fifteenth annual assembly of this Society began on the 11th, in the Lecture Hall of the Pharmacological Institute here. Jahn of Berlin spoke on the Physical Properties of Fluids, and Gans of Karlsbad communicated the results of experimental investigations of Diseases of the Kidneys. The second meeting was held on the 12th. Weissenberg of Kolberg spoke on the Most Urgent Hygienic Requirements of the German Health Resorts, and Liebreich on Natural and Artificial Mineral Waters. The third meeting was held on the 13th. Winternitz of Vienna discoursed on the Cold Water Treatment of Articular Rheumatism, Leyden on Diabetes, Müller of Berlin on Gymnastic Exercises for the Simultaneous Development of the Antagonistic Muscles, and Kolbe of Reinerz on the Effects of Mineral Waters in the Treatment of Phthisis. The fourth meeting was held on the 14th, Lenné of Neuenahr, Kallay of Karlsbad and Liebreich of Berlin spoke on Diabetes, Dührssen of Berlin on the Therapeutic Results of Baths in Diseases of Women, Marcus of Pyrmont and Senator of Berlin on the Treatment of Basedow's Disease, and Liebig of Reichenhall on Increased and Diminished Atmospheric Pressure. The fifth and last meeting was held on the evening of the 14th. Keller of Rheinfelden read a paper on the Use of Brine Baths containing 12 to 25 per cent. of Salt, Abel of Odessa on Mud and Brine Baths in the Health Resorts near Odessa, Saalfeld of Berlin on the Care of the Skin, Liebreich on the Bathing and Rubbing of New born Infants, Schubert of Reinerz on Bloodletting and Putzar of Königsbrunn on Neurasthenic Gastro-intestinal Atony.

The German Epidemic Bill.

A meeting was held for the discussion of the Epidemic Bill in the Imperial Home Office on the 14th inst. Secretary of State von Boetticher presided and the Prussian Minister of Ecclesiastical, Educational and Medical Affairs, with several counsellors of the medical department, the Director of the Imperial Office of Health, Professor Koch, and numerous representatives of the various German States were present.

The International Sanitary Conference

The King of Saxony received the delegates to the International Sanitary Conference on the 15th inst. and entertained them at a banquet, at which the Saxon Ministers and the members of the Diplomatic Corps were present.

Miscellaneous Items

Dr Ernst Siemerling, assistant in the Clinic for Mental Diseases at Berlin, has accepted the posts of Director of the Clinic for Mental Diseases at Tübingen and of professor there.

The general assembly of the Society of Prussian Medical Officials will be held in the Langenbeck House here on the 10th and 11th prox.

The German Anatomical Society will hold its annual meeting at Göttingen on May 21st, 22nd, 23rd, and 24th, Professor Waldeyer in the chair.

Berlin, March 20th.

Obituary.

SEPTIMUS W SIBLEY, F.R.C.S.

THE seventh son of the late Mr Robert Sibley, architect and surveyor of the county of Middlesex, the subject of this notice was born in Great Ormond street in 1831. He was educated first at a private school and then at University College School, London, where he obtained several prizes for mathematics pure and applied and for natural philosophy. He then attended lectures at University College under Professor de Morgan and at this time worked chiefly at higher mathematics and experimental philosophy with his friends St. William Flower, Dr Routh and the late Sir Robert Forster.

residence at Alnwick of about thirty years. I noted the banquet which was given him by the townspeople of Alnwick on his retirement. Dr Candlish, who was held in the greatest respect by all classes in the north of England and whose character was marked by a distinct individuality, was a nephew of the great Dr Candlish, of the Free Church of Scotland.

The late Dr Heath of Newcastle

I hear that the munificent bequests of the late Dr Heath, including £6000 for a residential hall in connexion with the Durham College of Medicine, Newcastle, have been paid over this week to the trustees. Dr Heath's bequests to educational and charitable objects amount to £30,000.

Newcastle-on Tyne, March 22nd.

IRELAND

(FROM OUR OWN CORRESPONDENT)

Royal College of Surgeons

A MEETING of the Fellows to consider the "Government of Ireland Bill" as affecting the future state of the College and the position and interests of its Fellows and Licentiates was held at the College on Saturday last, presided over by Mr Thornley Stoker, Vice President, in the absence of the President from illness. The following resolutions were proposed by Sir George Porter, Bart., seconded by Sir William Stokes, and, after considerable discussion, adopted by a large majority:—"That we protest against the passing of the Government of Ireland Bill now before Parliament, as, should it become law, it would seriously injure the College and be injurious to the interests of its Fellows and Licentiates, inasmuch as—firstly, that it imperils the existence of the Charter and of the College, secondly, that, the property of the College exclusive of its buildings being secured by mortgage on lands, its value will be depreciated, thirdly, that the moneys provided for medical charities (including Poor law, medical and sanitary services), amounting to about £100,000 a year, appear to be totally unprovided for, fourthly, that the Bill makes no provision for the registration of the members of the medical profession under the General Medical Council or for the control of that Council over medical education in Ireland, that as a result it is to be feared that students intending to practise outside Ireland will no longer be educated at home or take their diplomas from the Irish licensing bodies." The financial aspect of the Bill as it would affect the revenues of the college was the only part of the Bill permitted to be discussed.

Stewart Institution for Imbecile Children.

This institution has been in existence for twenty four years, and its usefulness is shown in the increasing contributions and the demand for additional accommodation. As to the proposed extension of the buildings, the committee are not yet in a position to undertake it, for the cost of carrying out the plans has been found to be higher than was originally estimated. Up to the present the funds available are about £5000, but at least as much more will be required before the principal portion of the work can be commenced. The postponement of the work has entailed great inconvenience, and not the least of the drawbacks attendant on the present limited accommodation is the entire inability of the management to provide the necessary arrangements called for by the friends of imbecile children who are in a position to pay for their maintenance. As this is a considerable source of income in similar establishments in England and elsewhere, there is reason to believe that the Stewart Institution suffers a large annual loss by being unable to meet such applications, and were the committee in a position to receive private pupils at suitable rates of payment it is certain they would be enabled to maintain a much larger number of free pupils than is possible at present.

Sanitary Institute Lectures

The first of a series of lectures organised by the Sanitary Institute of Great Britain and Ireland, under the auspices of the Corporation of Dublin, was delivered on Saturday by Sir Charles Cameron. They are chiefly intended for sanitary inspectors and candidates for that office, and will be followed by an examination for the certificates for sanitary inspectors given by the Sanitary Institute. Sir Charles Cameron's address referred to the benefits of sanitary legislation and

showed that the Corporation, by an expenditure of £600,000 in sanitary improvements, had caused the high fever death rate of Dublin to be now below that of the mean rate in the English towns. The lecturer pointed out how difficult it was in Dublin to have nuisances abated by giving notice, and that it was impossible to get more than 90 per cent. of them abated without tedious legal proceedings being taken, whilst in most English towns notices to abate nuisances were obeyed at once.

Kingstown Main Drainage

The Kingstown town commissioners have resolved that it is desirable to ascertain whether an extensive scheme of main drainage is necessary for their township, and with that object a special committee has been appointed to make the proper inquiries and to advise the board thereon. The committee will have power to make arrangements to complete the float experiments requisite to ascertain the direction of the tidal currents and, upon the rejection by the authorities of the Blackrock and Kingstown Drainage and Improvement Bill now before Parliament, to prepare and submit to the Commissioners such scheme as they may deem necessary for the effectual drainage of the district.

Cloyne Dispensary

The Local Government Board have not insisted upon the resignation of Mr Riordan, medical officer, on account of his long career of usefulness and at the unanimous request of the Dispensary Committee. There was a torchlight procession of his admirers when it became known that he would continue to act as medical officer of the district.

March 21st.

PARIS

(FROM OUR OWN CORRESPONDENT)

Suture of Ulnar Nerve Four Months after Section, Rapid Return of Sensation

ON March 7th M Berger presented to the Academy of Medicine a little girl whose ulnar nerve, divided by the bursting of a bottle, had been reunited by suture four months after the injury. At the time of the accident the ulnar artery had been tied, but the divided nerve had been left untouched. M Berger found the divided ends of the nerve separated by an interval of one centimetre, each end being the seat of a neuroma. These growths, together with a slender fibrous cord uniting them, were removed and the ends brought together with silk sutures. On the day following the operation the anaesthesia of the little and half the ring finger had disappeared, and the trophic troubles in their turn soon did the same. The child's hand no longer presents the appearance of *la grippe cubitale*, and the local muscular paralysis is no longer apparent. Professor Tillaux explains the rapid return of nerve function by the almost instantaneous re-establishment of the current brought about by the accurate apposition of the nerve ends. Both MM Tillaux and Nicaise have related cases where sensibility was restored five hours after paring and union of the cut ends of a nerve. In two cases, reported by MM Polaillon and Segond, the same result was observed a quarter of an hour after the operation. M Laborde expressed himself as not satisfied with M Tillaux's theory, and he proposes to initiate a discussion on the subject at no distant date.

The Consumption of Ice in Paris

Visitors to this "city of light" cannot fail to note the enormous consumption of ice in the cafés and restaurants, and many of them must have indulged in speculations on the origin of such a vast supply of the refreshing commodity. Most of it is natural ice collected during the winter months from various lakes in the neighbourhood of the capital. Of the total amount thus garnered (30,000 tons) the Lac Daumesnil at Vincennes is responsible for from 12,000 to 15,000 tons and the Bois de Boulogne lake for half that quantity. The remainder comes from ponds at La Briche, St Ouen, Chaville, St. Cloud, Château Frayet and Tournel. The original cost of this natural ice varies from three to four francs a ton. Of the artificial product the Société Anonyme des Glacières de Paris supplies 24,000 tons and the Société Anglaise from 2000 to 3000 tons, the manufacturing cost being eighteen or nineteen francs per ton. With regard to the natural ice I have already drawn attention to its frequent impurity. Take, for instance, the Daumesnil Lake, from which is drawn half the supply of

natural ice consumed in Paris. The *Médecine Moderne* informs its readers that a sewer opens at the top of that sheet of water and that, besides, it is fed by an artificial stream, which, rising in the plateau of Gravelle, crosses a large part of the Vincennes wood. A visit to that wood on a fine Sunday will easily enable the observant sanitarian to judge of the manner in which the waters of this artificial river are adulterated by the numerous holiday makers strolling on its banks. Until provisions are made by the authorities to safeguard the purity of the natural product I should strongly recommend visitors to this city who indulge in the consumption of ice to insist upon being supplied with that manufactured artificially by the companies above mentioned.

The Petroleum Treatment of Diphtheria

In the third number of the *Normandie Médicale* Dr Flahaut relates the history of an epidemic of diphtheria that occurred at La Neuville—Champ-d'Oisel—in 1891/92, seventy persons being attacked. In the first and earlier series of cases (thirty) reported the usual topical treatment (carbolic acid, sublimate, salicylic acid &c.) was followed, with the result that nine out of the thirty patients died. For the remaining forty, local applications of petroleum were employed, all the cases recovering. From the day on which this new treatment was instituted the mortality became suddenly nil. M. Flahaut says—"I commenced this mode of treatment on a little girl whose fauces tonsils and soft palate were covered with thick false membranes. From the very first applications of the petroleum the membranes were seen to whiten, retract and almost dissolve under the brush. The same evening she breathed more easily and expelled some membranous exudations. Five days later the child was, if not absolutely cured, out of danger and complete recovery was only a question of time. From that time forth I employed petroleum locally in all my cases and I congratulate myself on having done so, since they all recovered." A throat brush dipped into the petroleum and shaken free of any excess of the liquid is passed every hour or every two hours, according to the gravity of the case, over the parts covered by membrane. The application is said not to be painful—on the contrary, it produces a soothing effect. The only drawbacks are the disagreeable taste and odour of the petroleum. Membranes expelled by patients and received into capsules containing petroleum are almost totally dissolved after a gradual process of disintegration. The treatment lasted on an average a fortnight, at the end of which recovery generally occurred almost suddenly. The diagnosis was confirmed by the discovery of the Klebs Loeffler bacillus and by the superinfection in several instances of complications and sequelæ, such as bronchitis, broncho pneumonia, paralysis and albuminuria.

The Orchococcus

It has hitherto been taken for granted that the occurrence of orchitis—or rather epididymitis—in the course of an attack of gonorrhœa was due to the invasion of that organ by the migration of the gonococcus of Neisser. M. Huguoneng and Enaud (Académie des Sciences, Feb 27th) appear, however, to have successfully isolated the specific microbe of blennorrhagic epididymitis. The newly discovered micro-organism is a diplococcus of much the same shape as Neisser's gonococcus, but it is larger, the isolated coccus measuring about 1 μ . Like the gonococcus, it is discoloured by Gram's method, but it is distinguishable from it by the following properties: whilst the gonococcus is with difficulty cultivated even on human serum in which it dies at the end of two or three days, the orchococcus thrives well on peptone, peptonised gelatine, ordinary bouillon and alkaline solutions of casein and nuclein, maintaining in these different media the faculty of reproduction and the integrity of its forms for a year and longer. The orchococcus is frequently found in gonorrhœal pus during the first few days of the disease. It happens, however, sometimes that this pus sown upon gelatine yields no culture. Now when this is the case, such patients are never attacked with orchitis. If, on the contrary, pus thus sown on gelatine yields colonies of the micro-organism the onset of the testicular complication is to be feared. Negative cultivation results enable us therefore to foretell that the gonorrhœa will run its course without the epididymis being infected. The microbe exercises no action on the conjunctiva, the areolar tissue, the peritoneum, or on the urethra itself. On introducing the culture (on peptonised bouillon) into the testis of the dog an attack of orchitis is induced. The inflammatory products collected from the bouillon culture produce the same effects,

but act much more energetically, the orchitis induced being often accompanied by profuse suppuration and being sometimes followed by atrophy of the affected organ.

March 21st.

BERLIN

(FROM OUR OWN CORRESPONDENT)

The Balneological Society

THE discussions of the fifteenth annual assembly of this Society began on the 11th, in the Lecture Hall of the Pharmacological Institute here. Jahn of Berlin spoke on the Physical Properties of Fluids, and Gans of Karlsbad communicated the results of experimental investigations of Diseases of the Kidneys. The second meeting was held on the 12th. Weissenberg of Kolberg spoke on the Most Urgent Hygienic Requirements of the German Health Resorts, and Liebreich on Natural and Artificial Mineral Waters. The third meeting was held on the 13th. Winternitz of Vienna discoursed on the Cold Water Treatment of Articular Rheumatism, Leyden on Diabetes, Müller of Berlin on Gymnastic Exercises for the Simultaneous Development of the Antagonistic Muscles, and Kolbe of Reinerz on the Effects of Mineral Waters in the Treatment of Phthisis. The fourth meeting was held on the 14th, Lenné of Neuenahr, Kallay of Karlsbad and Liebreich of Berlin spoke on Diabetes, Dührssen of Berlin on the Therapeutic Results of Baths in Diseases of Women, Marcus of Pyrmont and Senator of Berlin on the Treatment of Basedow's Disease, and Liebig of Reichenhall on Increased and Diminished Atmospheric Pressure. The fifth and last meeting was held on the evening of the 14th. Keller of Rheinfelden read a paper on the Use of Brine Baths containing 12 to 25 per cent. of Salt, Abel of Odessa on Mud and Brine Baths in the Health Resorts near Odessa, Saalfeld of Berlin on the Care of the Skin, Liebreich on the Bathing and Rubbing of New born Infants, Schubert of Reinerz on Bloodletting and Putzar of Königsbrunn on Neurasthenic Gastro intestinal Atony.

The German Epidemic Bill

A meeting was held for the discussion of the Epidemic Bill in the Imperial Home Office on the 14th inst. Secretary of State von Boetticher presided and the Prussian Minister of Ecclesiastical, Educational and Medical Affairs, with several counsellors of the medical department, the Director of the Imperial Office of Health, Professor Koch, and numerous representatives of the various German States were present.

The International Sanitary Conference

The King of Saxony received the delegates to the International Sanitary Conference on the 15th inst. and entertained them at a banquet, at which the Saxon Ministers and the members of the Diplomatic Corps were present.

Miscellaneous Items

Dr Ernst Siemerling, assistant in the Clinic for Mental Diseases at Berlin, has accepted the posts of Director of the Clinic for Mental Diseases at Tübingen and of professor there.

The general assembly of the Society of Prussian Medical Officials will be held in the Langenbeck House here on the 10th and 11th prox.

The German Anatomical Society will hold its annual meeting at Göttingen on May 21st, 22nd, 23rd, and 24th, Professor Waldeyer in the chair.

Berlin, March 20th.

Obituary.

SEPTIMUS W SIBLEY, F.R.C.S.

THE seventh son of the late Mr Robert Sibley architect and surveyor of the county of Middlesex the subject of this notice was born in Great Ormond street in 1831. He was educated first at a private school and then at University College School, London, where he obtained several prizes for mathematics pure and applied and for natural philosophy. He then attended lectures at University College under Professor de Morgan and at this time worked chiefly at higher mathematics and experimental philosophy with his friends Sir William Flower, Dr Routh and the late Sir Robert Ker Porter.

a residence at Alnwick of about thirty years. I noted the banquet which was given him by the townspeople of Alnwick on his retirement. Dr Candlish, who was held in the greatest respect by all classes in the north of England and whose character was marked by a distinct individuality, was a nephew of the great Dr Candlish, of the Free Church of Scotland.

The late Dr Heath of Newcastle

I hear that the munificent bequests of the late Dr Heath, including £6000 for a residential hall in connexion with the Durham College of Medicine, Newcastle, have been paid over this week to the trustees. Dr Heath's bequests to educational and charitable objects amount to £30,000.

Newcastle on Tyne, March 22nd

IRELAND

(FROM OUR OWN CORRESPONDENT)

Royal College of Surgeons

A MEETING of the Fellows to consider the "Government of Ireland Bill" as affecting the future state of the College and the position and interests of its Fellows and Licentiates was held at the College on Saturday last presided over by Mr Thornley Stoker, Vice-President, in the absence of the President from illness. The following resolutions were proposed by Sir George Porter, Bart, seconded by Sir William Stokes, and, after considerable discussion, adopted by a large majority: "That we protest against the passing of the Government of Ireland Bill now before Parliament, as, should it become law, it would seriously injure the College and be injurious to the interests of its Fellows and Licentiates, inasmuch as—firstly, that it imperils the existence of the Charter and of the College, secondly, that, the property of the College exclusive of its buildings being secured by mortgage on lands, its value will be depreciated, thirdly, that the moneys provided for medical charities (including Poor law, medical and sanitary services), amounting to about £100,000 a year, appear to be totally unprovided for, fourthly, that the Bill makes no provision for the registration of the members of the medical profession under the General Medical Council or for the control of that Council over medical education in Ireland, that as a result it is to be feared that students intending to practise outside Ireland will no longer be educated at home or take their diplomas from the Irish licensing bodies." The financial aspect of the Bill as it would affect the revenues of the college was the only part of the Bill permitted to be discussed.

Stewart Institution for Imbecile Children.

This institution has been in existence for twenty four years, and its usefulness is shown in the increasing contributions and the demand for additional accommodation. As to the proposed extension of the buildings, the committee are not yet in a position to undertake it, for the cost of carrying out the plans has been found to be higher than was originally estimated. Up to the present the funds available are about £5000, but at least as much more will be required before the principal portion of the work can be commenced. The postponement of the work has entailed great inconvenience, and not the least of the drawbacks attendant on the present limited accommodation is the entire inability of the management to provide the necessary arrangements called for by the friends of imbecile children who are in a position to pay for their maintenance. As this is a considerable source of income in similar establishments in England and elsewhere, there is reason to believe that the Stewart Institution suffers a large annual loss by being unable to meet such applications, and were the committee in a position to receive private pupils at suitable rates of payment it is certain they would be enabled to maintain a much larger number of free pupils than is possible at present.

Sanitary Institute Lectures

The first of a series of lectures organised by the Sanitary Institute of Great Britain and Ireland, under the auspices of the Corporation of Dublin, was delivered on Saturday by Sir Charles Cameron. They are chiefly intended for sanitary inspectors and candidates for that office, and will be followed by an examination for the certificates for sanitary inspectors given by the Sanitary Institute. Sir Charles Cameron's address referred to the benefits of sanitary legislation and

showed that the Corporation, by an expenditure of £600,000 in sanitary improvements, had caused the high fever death rate of Dublin to be now below that of the mean rate in the English towns. The lecturer pointed out how difficult it was in Dublin to have nuisances abated by giving notice, and that it was impossible to get more than 90 per cent. of them abated without tedious legal proceedings being taken, whilst in most English towns notices to abate nuisances were obeyed at once.

Kingstown Main Drainage

The Kingstown town commissioners have resolved that it is desirable to ascertain whether an extensive scheme of main drainage is necessary for their township, and with that object a special committee has been appointed to make the proper inquiries and to advise the board thereon. The committee will have power to make arrangements to complete the float experiments requisite to ascertain the direction of the tidal currents and, upon the rejection by the authorities of the Blackrock and Kingstown Drainage and Improvement Bill now before Parliament, to prepare and submit to the Commissioners such scheme as they may deem necessary for the effectual drainage of the district.

Cloyne Dispensary

The Local Government Board have not insisted upon the resignation of Mr Rlordan, medical officer, on account of his long career of usefulness and at the unanimous request of the Dispensary Committee. There was a torchlight procession of his admirers when it became known that he would continue to act as medical officer of the district.

March 21st.

PARIS

(FROM OUR OWN CORRESPONDENT)

Suture of Ulnar Nerve Four Months after Section, Rapid Return of Sensation.

ON March 7th M Berger presented to the Academy of Medicine a little girl whose ulnar nerve, divided by the bursting of a bottle, had been reunited by suture four months after the injury. At the time of the accident the ulnar artery had been tied, but the divided nerve had been left untouched. M. Berger found the divided ends of the nerve separated by an interval of one centimetre, each end being the seat of a neuroma. These growths, together with a slender fibrous cord uniting them, were removed and the ends brought together with silk sutures. On the day following the operation the anesthesia of the little and half the ring finger had disappeared, and the trophic troubles in their turn soon did the same. The child's hand no longer presents the appearance of *la grappe cubitale*, and the local muscular paralysis is no longer apparent. Professor Tillaux explains the rapid return of nerve function by the almost instantaneous re-establishment of the current brought about by the accurate apposition of the nerve ends. Both MM Tillaux and Nicaise have related cases where sensibility was restored five hours after paring and union of the cut ends of a nerve. In two cases, reported by M. Polailon and Segond, the same result was observed a quarter of an hour after the operation. M Laborde expressed himself as not satisfied with M. Tillaux's theory, and he proposes to initiate a discussion on the subject at no distant date.

The Consumption of Ice in Paris

Visitors to this "city of light" cannot fail to note the enormous consumption of ice in the cafés and restaurants, and many of them must have indulged in speculations on the origin of such a vast supply of the refreshing commodity. Most of it is natural ice collected during the winter months from various lakes in the neighbourhood of the capital. Of the total amount thus garnered (30,000 tons) the Lac Daumesnil at Vincennes is responsible for from 12,000 to 15,000 tons and the Bois de Boulogne lake for half that quantity. The remainder comes from ponds at La Briche, St. Ouen, Chaville, St. Cloud, Château Frayet and Tournell. The original cost of this natural ice varies from three to four francs a ton. Of the artificial product the Société Anonyme des Glacières de Paris supplies 24,000 tons and the Société Anglaise from 2000 to 3000 tons, the manufacturing cost being eighteen or nineteen francs per ton. With regard to the natural ice I have already drawn attention to its frequent impurity. Take, for instance, the Daumesnil Lake, from which is drawn half the supply of

IMPROVED STEAMSHIPS—Improvements are gradually being introduced into the construction of steamers in order to render them more and more suitable for the conveyance of invalids in search of health in other climates. The *Ave*, a first-class mail and passenger steamer belonging to the Royal Mail Steam-Packet Company is a very fine specimen of a modern vessel. Accommodation is provided for 215 first class passengers, thirty six second class and 350 emigrants. The ship is built of steel and is divided into eleven compartments by ten watertight bulkheads and will be lighted by electricity throughout.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY—At a meeting of the council of this society on Feb. 28th a large number of new members were elected and it was announced that new districts had been formed in East Central London, Wandsworth and Plymouth. Several cases were reported in which the efforts of the society had been successful in checking illegal or unprofessional practice, and the secretaries were instructed to take action in other cases which were brought under the notice of the society. It was resolved that arrangements be made to hold a dinner after the annual meeting on June 1st, or on a subsequent Tuesday or Thursday in that month. Dr Heron, on behalf of the Finance Committee, presented a satisfactory interim report of the financial position of the society.

ROYAL MICROSCOPICAL SOCIETY—At the meeting of this Society on the 15th inst. an electric turntable was exhibited on behalf of Mr Payne of Newcastle. It was of the ordinary pattern, having an electric motor fitted beneath the plate, the whole was caused to revolve by the current from a chromate battery cell. Dr W H Dallinger gave a brief description of Professor Bütschli's experiments on the so-called artificial protoplasm and said that he could not suppose that anyone looking at these forms would regard them as in any way allied to living matter. Other specimens were shown and short papers were read, after which Professor Bell introduced some remarks from the pen of Dr G M. Giles on Certain Cystic Worms which Simulate the Appearances of Tuberculosis. Dr Hebb said he had never met in England with any worms such as those described in the paper. Professor Bell thought the observations of Dr Giles were of considerable importance, because, if the large number of animals which were killed as being tuberculous were really not so, it might be possible to prevent their destruction. A paper by Dr Stokes, On New Brackish Water Infusoria from the United States, was taken as read.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND—The quarterly meeting of this Association was held on the 9th inst. in the Medical Institution, Liverpool, under the presidency of Dr Baker. Dr Wilesworth Ramhill Asylum, read a paper on "General Paralysis occurring about the Period of Puberty." Up to the present time it has been commonly supposed that the disease came on only in adult life, but he cited cases which he had treated showing that adolescence was by no means exempt from general paralysis. A discussion followed, in which the facts and conclusions of Dr Wilesworth were confirmed.—Dr F St. John Bullen gave an account of the out-patient system now being practised at the West Riding Asylum, Wakefield, but he was unable to say whether the results were of a satisfactory character. From the discussion which took place, the system, on the whole, was not approved of.—Dr J Cumming Mackenzie read notes showing that it is possible for the Celtic Highlander to acquire general paralysis and allied neuroses at home, but at the same time he demonstrated that there was less general paralysis among the Celts than among the Saxons.—It was resolved to invite subscriptions in aid of the family of the late Dr Ball, who died at Paris recently. In the evening the members and their friends dined together at the Adelphi Hotel, under the chairmanship of the President, Dr Baker. Among those present were the mayor (Mr R D Holt) Mr W S Barrett, Mr Thomas Snape, M.P., Dr Glynn and several members of the profession residing in Liverpool. After the loyal toasts had been proposed by the chairman and duly honoured Dr Savage submitted "The Houses of Parliament." Mr Thomas Snape, M.P. in responding bore testimony to the self-sacrificing efforts of the medical staff of Ramhill Asylum, and suggested that it would be a very desirable thing to ask Parliament to empower the County Councils to supply funds for the training of nurses.

NOTES IN PARLIAMENT

Parish Councils

THE long-expected Bill dealing with parish councils has been introduced into the House of Commons by the President of the Local Government Board. Mr Fowler had no difficulty in showing the anomalies of local government in rural districts and how any inhabitant might be governed by the vestry the burial board, a highway board, the school board, the guardians and the quarter sessions. His proposal that parish councils should be constituted to replace existing administrations is the natural sequel to the passing of the Local Government Act of 1883 and upon these councils will devolve if the Bill pass in its present form, certain important sanitary duties. Thus the council may provide recreation grounds and have power of utilising any water supply within a parish, as well as powers to deal with ditches drains stagnant water and any matters likely to be prejudicial to health. At the present time it is the statutory duty of the district councils—Mr Fowler says he hopes to make it more binding upon them—to see to the water supply and to the sanitary requirements of every parish within their areas, and as we understand it, the parish council is to have power of representation to the county council when the district council is in default. The details of the administration which is thus foreshadowed cannot be fully understood until the Bill is printed and under these circumstances it is desirable to postpone any discussion of the subject. We shall therefore hope to revert to it very shortly.

The General Medical Council.

The accounts of the General Medical Council and Branch Councils and of the Dental Registration Fund for 1892 have been presented to the two Houses of Parliament.

The Food and Drugs Act

At the House of Commons on Wednesday a deputation from the committee of the Federation of Grocers' Associations in the United Kingdom waited upon Dr Cameron M.P. with reference to the Bill of which he has charge for amending the Sale of Food and Drugs Act of 1875. The deputation expressed general approval of the provisions of the Bill. They agreed that it was quite as necessary to deal with wholesale as with retail traders, and they submitted that the invoice of the wholesale trader should be regarded as a warranty so far as the retail trader was concerned. With regard to the provision as to the mixture of coffee with chicory the members of the deputation, whilst appreciating its merits were afraid difficulty might arise in getting magistrates to carry it out strictly. Dr Cameron thanked the deputation for their sympathy and their promises of support. As to the percentage of water to be allowed in butter, he informed them that he had not been able to fill in any figures because of the great variety of practice in different parts of the country, both on the part of magistrates and of analysts. Evidence would be required to be taken on the point, and he hoped with this view that the Bill would be referred to a select committee. In promoting the Bill he was glad to find that he had the sympathy both of the traders and of the analysts. In such circumstances he looked confidently to the future. Before leaving the room the deputation thanked Dr Cameron for receiving them.

Cholera Hospitals (Ireland) Bill.

In the House of Commons on the 16th inst., this Bill passed through Committee and was read a third time.

Tuberculosis.

In reply to Mr Field Mr H. Fowler said he was informed by the Secretary of the Royal Commission on Tuberculosis that it was impossible to fix the precise date of the termination of the work of the Commission and of the presentation of their report. It was hoped that the experiments now proceeding would have terminated by the end of April, and by the end of June it was anticipated, the whole of the microscopical investigations would be complete and the reports of the subcommittees be in the hands of the Commission. The question of compensation would be reserved.

The Disposal of the Dead

Dr Cameron who had given notice to move an amendment to the terms of the motion that a select committee be appointed to inquire into the sufficiency of the existing law as to the disposal of the dead congratulated the Government on their decision to grant that committee and said that in England alone 50,000 interments took place yearly without proper certificates of death being given.—Dr Farquharson, who had arranged to second the amendment, joined his congratulations with those of Dr Cameron and would have been prepared to enforce the need of such an inquiry as that contemplated.

The Supply of Water to the Metropolis

Mr Stuart on the order for the second reading of the East London Water Bill, moved the rejection of the measure a course in which he was sustained he said by the decision of the London County Council. He maintained that the Bill was inopportune since the report of the Commission on the whole subject of the metropolitan water supply was likely to be quickly forthcoming.—Mr Bonhôte deprecated opposition to the Bill, and Mr Mellor thought the House would incur grave responsibility by rejecting the measure at that stage. The House however testified its willingness to accept that responsibility by throwing out the Bill by a majority of 176 against 152.

Fur and Glanders.

In answer to questions put by Mr Foster Mr Campbell Bannerman said that for the last five years the horses of the army had been free

At this period of his life he desired to enter upon a mathematical career. He entered as a student at the Middlesex and University College Hospitals in the year 1848, attending lectures at the latter and clinical work at the former school. Whilst at University College Hospital he obtained the gold medal in medicine, the first silver medal being obtained by Dr Bartlett of Ipswich and the second silver medal by Sir Joseph Lister. He also obtained the silver medal in surgery the gold medal being carried off by Mr J S Gamgee, and the second silver one by Sir Joseph Lister.

His chief contemporaries at the hospital were Wilham Flower, Joseph Lister and William Roberts. He became a Member of the Royal College of Surgeons in the year 1852 and a Fellow in 1857. At the Middlesex Hospital he was at first house surgeon, and then medical registrar from 1853 to 1860. He was afterwards appointed lecturer in pathology, which post he held for ten years. In 1856 Mr Sibley became partner with Mr Thomas Farquhar Chilver, succeeding Mr Martin Tupper. This practice was one of the leading ones of the day, being founded by Sir Walter Farquhar, physician to George IV. He was an active member of the Middlesex Hospital Medical Committee for many years and a prominent member of the British Medical Association. He afterwards became a Fellow of the Royal Medical and Chirurgical Society, a member of the Council of the Clinical Society and a member of the Pathological Society. In 1886 Mr Sibley was elected to the Council of the Royal College of Surgeons representing the general practitioners, the duties of which post he discharged for several years. He was also chairman of the Managing Committee of the Dental Hospital of London for ten years, succeeding his friend Campbell de Morgan. His chief contributions to the literature of medical science were "History and Description of the Cholera Epidemic in London in 1854" in the *Royal Medical and Chirurgical Society's Transactions*, and "Statistics on Cancer," "Fibrinous Obstruction of Arteries," "The Nature of Colloid" &c. He married a daughter of the late Sir Robert Carden, Bart., M.P. His widow, two sons and five daughters, together with a brother, General T H Sibley, J.P., and his sister, Lady Tomes, the wife of Sir John Tomes, F.R.S., survive him.

DR. RICHARD ALFRED O'BRIEN

AN Irish practitioner of much experience and skill in Oriental maladies, Dr O'Brien had for some years lived in retirement in a Florentine villa, where, on Tuesday, Feb 28th, he passed away after a lingering illness. His professional studies were prosecuted partly in Dublin and partly in Pennsylvania, at which latter school he graduated M.D. in 1855. In 1864 he qualified as Licentiate in Medicine at the King and Queen's College of Physicians of Ireland, taking its diploma in Midwifery in the same year, whilst, also in 1864, he became Licentiate in Surgery of the Royal College in Edinburgh. Of the latter College he was elected a Fellow in 1882, having become a Member of the former in 1881. His professional life was spent chiefly in Hong Kong, where he steadily rose to be the trusted and esteemed consultant of a large *chentele*, American as well as British. About ten years ago he withdrew from regular practice and devoted much of the fortune he had amassed to the promotion of the charitable objects dear to him throughout life.

DR MASSIMILIANO CARTEI

DEATH, which has of late been busy in the Italian ranks of the profession, has removed few abler or more accomplished practitioners than Dr Cartei of the commune of Brozzi in Tuscany. Born in 1827, he was, like many of his compatriots of that generation swept into the revolutionary vortex, out of which emerged Italy "one and independent." Experience in camp and on battlefield was not thrown away upon him, but gave to his medical studies a seriousness and a practical efficacy which reacted for good throughout his academical career. Shortly after the upheaval of 1848 he resumed attendance at the Pisa School, and having graduated there he was appointed assistant physician in the "Arcispedale" of Santa Maria Nuova in Florence. Thereafter he rejoined his father (also a medical practitioner) and, having settled in the commune of Brozzi, was presently engaged in combating the terrible cholera explosion of 1855. By his energetic philanthropy he founded first an asylum for the sick poor and then a hospital, his experience of the epidemic having taught him how signally visitations of that kind are cut short or mitigated, and their professional teaching utilised, by such institutions, well appointed and on an adequate scale. By

1887 his health constrained his retirement to Florence, where, to the regret of a wide circle of friends of all professions, he died on Feb 23rd.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At a congregation held on the 18th inst. the degree of Bachelor of Medicine and Surgery was conferred on the following gentlemen—

Herbert John Paterson, Trinity Percival Horton-Smith St. John's, Reginald Darby Randall Crofton Atkins Clare John Shepperson Baraes Pembroke George William Harvey Bird, Emmanuel.

CORSTORPHINE CONVALESCENT HOME.—On Wednesday, March 15th, this institution, to which most of the convalescents from the Edinburgh Royal Infirmary belong was reopened after alterations by the Marchioness of Tweeddale.

EPSOM COLLEGE NATURAL HISTORY SOCIETY.—The report of this society for the past year gives a very favourable account of the work that has been accomplished in the various sections since the last statement was issued. It is very gratifying to find that the interest heretofore exhibited by the students of the college in the aims and objects of the society shows no sign of falling off, but rather goes on increasing from year to year. A society such as the one under notice must prove a useful auxiliary to the scholastic work usually undertaken in schools and colleges.

A JOINT HOSPITAL FOR HALIFAX.—On the 16th inst. a meeting of representatives of sanitary authorities of Halifax and its vicinity was held in the Town Hall to consider the advisability of forming a joint hospital for the area. The Mayor, who presided, said that Halifax was now provided with a small pox hospital, but there was no fever hospital or building specially devoted to the reception of persons suffering from contagious diseases. It was, however, desirable that a hospital for this purpose should be provided, the benefits of which might be participated in by surrounding districts. Though there were a few dissentients at the meeting the proposition gained the support of the great majority of those present.

BRITISH MEDICAL TEMPERANCE ASSOCIATION.—A general meeting was held on March 17th at the London Temperance Hospital by permission of the board, and was well attended. Dr B W Richardson, F.R.S., read a paper entitled a Review of Twelve Months' Medical Practice in the Wards of the London Temperance Hospital, which consisted of a summary of the nature and results of his first completed 200 cases with notes of the treatment pursued in some of them. Of these 58 per cent recovered, 22 per cent were relieved, 5.5 per cent were unrelieved and 14.5 per cent died. The cases were admitted as in other hospitals and many were severe. No alcohol had been administered in any case or in any form and the results had been satisfactory. He had largely employed inhalations of oxygen, peroxide of hydrogen and ozonic ether. Remarks were made by Dr Norman Kerr, Dr Moir and Dr Ridge, the last speaker, as a physician of the same hospital, testifying to his surprise and gratification at the results obtained.

MASON COLLEGE, BIRMINGHAM.—Mr Oliver Pemberton, F.R.C.S., J.P., was elected balliff of the Trust and President of the Council at the twenty second annual meeting of the trustees on the 23rd ult. In order to comply with the wishes of his colleagues on the governing body, that he should preside over their deliberations during the ensuing year, Mr Pemberton resigned his position, as we briefly announced last week, as Queen's co-Professor of Surgery. The council signified their acceptance of the resignation in the following terms—"That in accepting Mr Oliver Pemberton's resignation of the chair of surgery the council desire to record their sense of the great value of his services to the Birmingham School of Medicine for the long and unbroken period of nearly thirty years, as a college and clinical teacher, and particularly as Professor of Surgery for twenty five years. The council hereby express their strong desire that Mr Pemberton will consent to accept the position of an Emeritus Professor of Surgery in the College, in order that by this mark of well deserved recognition and distinction his name may still remain connected with the medical school with which he has been for many years so intimately, usefully, and honourably associated."

IMPROVED STEAMSHIPS—Improvements are rapidly being introduced into the construction of steamers in order to render them more and more suitable for the conveyance of invalids in search of health in other climates. The *Alce*, a first-class mail and passenger steamer belonging to the Royal Mail Steam-Packet Company, is a very fine specimen of a modern vessel. Accommodation is provided for 215 first class passengers, thirty six second class and 350 migrants. The ship is built of steel and is divided into seven compartments by ten watertight bulkheads and will be lighted by electricity throughout.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY—At a meeting of the council of this society on Feb 28th a large number of new members were elected, and it was announced that new districts had been formed in East Central London, Wandsworth and Plymouth. Several cases were reported in which the efforts of the society had been successful in checking illegal or unprofessional practice, and the secretaries were instructed to take action in other cases which were brought under the notice of the society. It was resolved that arrangements be made to hold a dinner after the annual meeting on June 1st, or on a subsequent Tuesday or Thursday in that month. Dr Heron, on behalf of the Finance Committee, presented a satisfactory interim report of the financial position of the society.

ROYAL MICROSCOPICAL SOCIETY—At the meeting of this Society on the 15th inst. an electric turntable was exhibited on behalf of Mr Payne of Newcastle. It was of the ordinary pattern, having an electric motor fitted beneath the plate, the whole was caused to revolve by the current from a bichromate battery cell. Dr W H Dallinger gave a brief description of Professor Bütschli's experiments on the so-called artificial protoplasm and said that he could not suppose that anyone looking at these forms would regard them as in any way allied to living matter. Other specimens were shown and short papers were read, after which Professor Bell introduced some remarks from the pen of Dr G M. Giles on Certain Cystic Worms which Simulate the Appearances of Tuberculosis. Dr Hebb said he had never met in England with any worms such as those described in the paper. Professor Bell thought the observations of Dr. Giles were of considerable importance, because, if the large number of animals which were killed as being tuberculous were really not so, it might be possible to prevent their destruction. A paper by Dr Stokes, On New Brackish Water Infusoria from the United States, was taken as read.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND—The quarterly meeting of this Association was held on the 9th inst. in the Medical Institution, Liverpool, under the presidency of Dr Baker. Dr Wilesworth, Rainhill Asylum, read a paper on "General Paralysis occurring about the Period of Puberty." Up to the present time it has been commonly supposed that the disease came on only in adult life, but he cited cases which he had treated showing that adolescence was by no means exempt from general paralysis. A discussion followed, in which the facts and conclusions of Dr Wilesworth were confirmed.—Dr F St John Bullen gave an account of the out-patient system now being practised at the West Riding Asylum, Wakefield, but he was unable to say whether the results were of a satisfactory character. From the discussion which took place, the system, on the whole, was not approved of.—Dr J Cumming Mackenzie read notes showing that it is possible for the Celtic Highlander to acquire general paralysis and allied neuroses at home, but at the same time he demonstrated that there was less general paralysis among the Celts than among the Saxons.—It was resolved to invite subscriptions in aid of the family of the late Dr Ball, who died at Paris recently. In the evening the members and their friends dined together at the Adelphi Hotel, under the chairmanship of the President, Dr Baker. Among those present were the mayor (Mr R. D. Holt), Mr W S. Barrett, Mr Thomas Snape, M.P., Dr Glynn and several members of the profession residing in Liverpool. After the loyal toasts had been proposed by the chairman and duly honoured, Dr Savage submitted "The Houses of Parliament." Mr Thomas Snape, M.P. in responding, bore testimony to the self-sacrificing efforts of the medical staff of Rainhill Asylum, and suggested that it would be a very desirable thing to ask Parliament to empower the County Councils to supply funds for the training of nurses.

NOTES IN PARLIAMENT

Parish Councils

THE long-expected Bill dealing with parish councils has been introduced into the House of Commons by the President of the Local Government Board. Mr Fowler had no difficulty in showing the anomalies of local government in rural districts and how any inhabitant might be governed by the vestry the burial board, a highway board the school board, the guardians and the quarter sessions. His proposal that parish councils should be constituted to replace existing administrations is the natural sequel to the passing of the Local Government Act of 1883 and upon these councils will devolve, if the Bill pass in its present form, certain important sanitary duties. Thus the council may provide recreation grounds and have power of utilising any water supply within a parish as well as powers to deal with ditches drains stagnant water and any matters likely to be prejudicial to health. At the present time it is the statutory duty of the district councils—Mr Fowler says he hopes to make it more binding upon them—to see to the water supply and to the sanitary requirements of every parish within their areas and as we understand it, the parish council is to have power of representation to the county council when the district council is in default. The details of the administration which is thus foreshadowed cannot be fully understood until the Bill is printed, and under these circumstances it is desirable to postpone any discussion of the subject. We shall therefore hope to revert to it very shortly.

The General Medical Council.

The accounts of the General Medical Council and Branch Councils and of the Dental Registration Fund, for 1892 have been presented to the two Houses of Parliament.

The Food and Drugs Act

At the House of Commons on Wednesday a deputation from the committee of the Federation of Grocers' Associations in the United Kingdom waited upon Dr Cameron M.P. with reference to the Bill of which he has charge for amending the Sale of Food and Drugs Act of 1875. The deputation expressed general approval of the provisions of the Bill. They agreed that it was quite as necessary to deal with wholesale as with retail traders, and they submitted that the invoice of the wholesale trader should be regarded as a warranty so far as the retail trader was concerned. With regard to the provision as to the mixture of coffee with chicory the members of the deputation whilst appreciating its merits were afraid difficulty might arise in getting magistrates to carry it out strictly. Dr Cameron thanked the deputation for their sympathy and their promises of support. As to the percentage of water to be allowed in butter he informed them that he had not been able to fill in any figures because of the great variety of practice in different parts of the country, both on the part of magistrates and of analysts. Evidence would be required to be taken on the point, and he hoped with this view that the Bill would be referred to a select committee. In promoting the Bill he was glad to find that he had the sympathy both of the traders and of the analysts. In such circumstances he looked confidently to the future. Before leaving the room the deputation thanked Dr Cameron for receiving them.

Cholera Hospitals (Ireland) Bill.

In the House of Commons on the 16th inst., this Bill passed through Committee and was read a third time.

Tuberculosis.

In reply to Mr Field, Mr H. Fowler said he was informed by the Secretary of the Royal Commission on Tuberculosis that it was impossible to fix the precise date of the termination of the work of the Commission and of the presentation of their report. It was hoped that the experiments now proceeding would have terminated by the end of April, and by the end of June, it was anticipated, the whole of the microscopical investigations would be complete and the reports of the subcommittees be in the hands of the Commission. The question of compensation would be reserved.

The Disposal of the Dead

Dr Cameron, who had given notice to move an amendment to the terms of the motion that a select committee be appointed to inquire into the sufficiency of the existing law as to the disposal of the dead congratulated the Government on their decision to grant that committee and said that in England alone 50,000 interments took place yearly without proper certificates of death being given.—Dr Farquharson, who had arranged to second the amendment, joined his congratulations with those of Dr Cameron and would have been prepared to enforce the need of such an inquiry as that contemplated.

The Supply of Water to the Metropolis

Mr Stuart on the order for the second reading of the East London Water Bill, moved the rejection of the measure a course in which he was sustained he said by the decision of the London County Council. He maintained that the Bill was inopportune since the report of the Commission on the whole subject of the metropolitan water supply was likely to be quickly forthcoming.—Mr Boulnois deprecated opposition to the Bill, and Mr Mellor thought the House would incur grave responsibility by rejecting the measure at that stage. The House however testified its willingness to accept that responsibility by throwing out the Bill by a majority of 170 against 152.

Farcy and Glanders.

In answer to questions put by Mr Foster Mr Campbell Bannerman said that for the last five years the horses of the army had been free

from farcy and glanders as a result of good sanitary measures and precautions against contagion.—Speaking for his department, Mr Gardner said he regretted that the London County Council had not fallen in with his views with regard to the justice of compensating local authorities for the slaughter of diseased animals in compliance with the order issued in September last. But he believed nevertheless that the enforcement of the other terms of the order had been attended with success so that the number of affected animals had shown a considerable falling off. Under these circumstances he did not contemplate taking any further steps at present.

Vaccination.

Mr A. C. Morton, Dr Farquharson, and Mr Picton severally put questions on the subject of the issue of the Vaccination Commission and Mr Asquith assured the hon. members that the Commission had presented an interim report which was characterised by unanimity. He should therefore be prepared to introduce a Bill at the earliest available opportunity—probably in the course of a few days.

Lunacy Certificates in Ireland. *

Mr Maurice Henly asked the Chief Secretary to the Lord Lieutenant of Ireland with reference to the new practice recently introduced with regard to the transfer of dangerous lunatics from workhouses to district asylums in Ireland, whether hitherto as a preliminary to such transfer an order was first obtained from two justices under the Act 30 and 31 Vic. c. 115 s. 10 on a certificate from the dispensary doctor whether there had been any change in the law enabling this order and certificate to be dispensed with whether it was the practice now to transfer such lunatics in the same manner as if they were harmless pauper lunatics—i.e., without a magistrate's order and on the certificate of the workhouse doctor merely and on what authority this change of practice was based.—Mr John Morley replied that he was informed that no such practice as the hon. member referred to had been introduced. As to the second paragraph there had been no change in the law to this effect. As to the third, persons admitted to district asylums as dangerous lunatics required a committal order signed by two justices and a certificate by the dispensary medical officer. Of course if the hon. member was aware of any case in which he was advised that there had been a departure from the law, he (Mr Morley) would inquire into it.

Cases of Supposed Infectious Disease.

On the 20th inst. Mr Macdonald drew attention by a question addressed to the President of the Local Government Board to a report which recently appeared in the public press wherein it was stated that last year owing to mistaken diagnosis 401 persons were removed to fever and small pox hospitals whereas none of these individuals were suffering from either of these diseases and 102 of them had lost their lives in consequence of such removal.—Mr H. Fowler said that 450 of the number above mentioned were cases in which admission was granted upon certificates which were afterwards found to be incorrect. The diseases from which those patients really suffered were ascertained by diagnosis after admission, and death ensued in 97 cases. It was utterly untrue that the deaths were due to the removal of the patients to the asylums.

County Medical Officers in Scotland.

Sir G. Trevelyan said, in reply to a question put by Dr Farquharson that by Clause 62 of the Local Government Act for Scotland it was enacted that it was for the county councils to determine whether or not their medical officers were to be debarred from private practice. In distributing the grant of £15,000 provided by Parliament amongst the counties of Scotland in aid of their medical expenditure it was made a condition by the Scotch Office that none of that grant should go to a county where the medical officer took private practice. Inasmuch however as Parliament clearly intended that the matter should be left to the discretion of the local body he (Sir G. Trevelyan) had ceased to exact any condition with regard to the point in question. [This subject, it will be recollected, was dealt with by us in a leading article last week.]

Parish Councils

On the 21st inst. Mr H. Fowler introduced a Bill to make larger provision for local government in England and Wales and in furtherance of an implied understanding that the Act of 1889 needed more legislation to make it complete. The parish would be the primary unit of local administration in rural districts. The vestries would be abolished and the civil parish would be alone recognised and dealt with. In every parish of 800 inhabitants and upwards a council would be established which would appoint overseers of the poor. To this council the whole machinery of the Allotments Act would be transferred and new powers would be given to it. By the Bill a district council could delegate to a parish council any power which might be entrusted to a parochial committee under the Public Health Act. Parishes having a population under 800 inhabitants would be grouped with other parishes. This measure, if passed, would effect radical changes in the machinery by which parish affairs had hitherto been conducted. It met with great favour by the bulk of the members present and was read a first time.

Hours of Labour in Shops

Sir J. Lubbock moved a resolution expressive of the opinion of the House that excessive and long-continued labour in shops is injurious to the comfort and well-being of persons engaged therein. He alluded to the legislation which had already been adopted in favour of factory workers and argued that shop assistants needed and might claim, relief in the same direction. He enforced his plea by reference to the report of the Parliamentary committee appointed in 1888 the members of which were unanimously of opinion that an Act of Parliament was necessary to curb the evil attending prolonged labour in shops. The workers themselves for the most part approved and sympathised with the efforts put forth to shorten the hours devoted to such work which had to be carried on often with defective light and in impure air. The motion was seconded by Mr Bartley and was supported by several members. Mr Asquith expressed his approval of the resolution which was unanimously agreed to.

Working Men's Dwellings Bill.

On Thursday Mr Wrightson moved the second reading of this Bill, which did not he said, propose to aid a man financially except for the purpose of acquiring a dwelling for himself, and this result, he maintained, could be better achieved by the instrumentality of the State than by means of a building society.—Mr H. Fowler on behalf of the Government, offered no opposition to the motion, and the Bill was read a second time and referred to a committee.

Sale of Intoxicating Liquors.

The second reading of the Bill for the more effectual control of the liquor traffic was moved by Mr Bolitho. By this measure it was proposed that a licensing authority should be established which should consist of not more than twelve members and to whom should be transferred the powers at present exercised by the licensing justices.—The Marquis of Carmarthen pointed out certain differences between the measure under discussion and that introduced by the Government, and moved that the Bill be read a second time this day six months.—The Chancellor of the Exchequer said that in that Bill the licensing board would have the power not only to limit the number of licenses but to extinguish them. As far as the Government were concerned they cordially supported the second reading of the Bill. Other speakers followed, and in the end the debate was adjourned.

Appointments.

For applicants for Vacancies Secretaries of Public Institutions, and for possessing information suitable for this column are invited to send it to THE LANCET Office directed to the Sub-Editor, not later than 11 o'clock on the Thursday morning of each week for publication in its next number

ALFRED W. A. H. L.R.C.P. Lond. L.R.C.S. Edin. has been appointed Medical Officer for the Isolation Hospital, Guildford.

ANDREW C. HENSON L.R.C.P. Lond. M.R.C.S. L.S.A. has been appointed Resident Clinical Assistant to the St. Marylebone Infirmary, vice G. Thornton, M.D., resigned.

DAVID G. H. L.R.C.P. L.M. Edin. L.F.P.S. Glasg. has been reappointed Medical Officer of Health for the Brynmawr Urban Sanitary District.

DR. F. J. M.B. C.M. Edin. has been appointed Medical Officer for the North Western Sanitary District of the Chester Union.

DR. ALBERT L.R.C.P. Lond. M.R.C.S. has been appointed Medical Officer to the Bristol Dispensary.

DR. D. B. M.B. C.M. Edin. has been appointed Medical Officer for the Spalding Sanitary District of the Roedale Union, vice Turner, resigned.

DR. G. B. L.R.C.P. L.M. L.R.C.S. Edin. has been appointed Medical Officer for the Bishton Sanitary District of the Blackburn Union.

DR. MAX F. J. M.B., B.S. Lond. has been appointed House Physician to Guy's Hospital.

DR. A. M. M.B., B.S. Lond. has been appointed Assistant House Physician to Guy's Hospital.

DR. W. H. M.R.C.S. has been appointed Medical Officer for the Third Sanitary District of the Wellington (Som.) Union.

DR. J. C. M.B., B.S. Lond. has been appointed Assistant House Physician to Guy's Hospital.

DR. P. A. L.D.S. R.C. Eng. has been appointed Honorary Dentist to the Dartmouth Cottage Hospital.

DR. H. M. C. W., L.R.C.P. Irel. has been appointed Medical Officer for the St. Laurence's Sanitary District of the Carlisle Union, vice Downe, resigned.

DR. T. E. M.B. B.S. Lond. F.R.C.S. has been appointed House Surgeon to Guy's Hospital.

DR. ERNEST L.R.C.P. Lond. M.R.C.S. has been appointed Second Assistant Medical Officer to the Levesden Asylum, Kings Langley.

DR. WILL. S. L.R.C.P. Edin. & L.M. M.R.C.S. has been appointed Medical Officer and Public Vaccinator to the Bildeston District of the Cosford Union also Medical Officer to the Cosford Union Workhouse vice Grosse, resigned.

DR. MONTAGUE F. L.D.S. Eng. has been appointed Assistant Dental Surgeon to Guy's Hospital.

DR. A. B. L.R.C.P. Lond. M.R.C.S. has been appointed Medical Officer for the Stradbroke Sanitary District of the Horne Union, vice Thomas, resigned.

DR. A. E. M.R.C.S. L.R.C.P. has been appointed House Surgeon to Guy's Hospital.

DR. E. B. M.R.C.S. L.R.C.P. has been appointed House Physician to Guy's Hospital.

DR. G. M.B. C.M. Glasg. has been reappointed Medical Officer of Health for the Patheley-bridge Rural Sanitary District.

DR. ALFRED DONALD M.A. M.B., C.M. Edin. has been appointed House Surgeon and Secretary to the Stamford, Rutland and General Infirmary vice Crisp, resigned.

DR. ARTHUR E. M.R.C.S. L.R.C.P. Lond. has been appointed Physician's Assistant to the Bristol General Hospital.

DR. C. S. M.B., B.S. Lond. has been appointed Assistant House Surgeon to Guy's Hospital.

DR. F. M. M.B. M.S. Edin. has been appointed Medical Officer for the Fourth Sanitary District of the Hamilton Union.

DR. J. L. M.B., M.S. Edin. has been appointed Medical Officer for the Sandfield Sanitary District of the Todmorden Union vice Measures, resigned.

DR. W. L.R.C.P. Lond. M.R.C.S. has been appointed Medical Officer of the Workhouse Parish of Birmingham, vice Rowlands, resigned.

DR. ERNEST L.R.C.P. Lond. L.S.A. has been appointed Honorary Medical Officer to the Cripples Home, Marylebone-road W.

DR. HAROLD L.D.S. Eng. has been appointed Assistant Dental Surgeon to Guy's Hospital.

DR. T. R. M.B. B.S. Lond. has been appointed Assistant House Surgeon to Guy's Hospital.

DR. SIDNEY W. E. M.B., B.S. Lond. has been appointed Honorary Assistant Surgeon to the Nottingham Hospital for Women.

DR. F. L.R.C.P. Lond. M.R.C.S. has been appointed Honorary Surgeon to the Doncaster Infirmary and Dispensary vice McKay, resigned.

DR. C. H. M.R.C.S. L.S.A. has been appointed Medical Officer of Health to the Midmore Norton Local Board.

DR. HENRY M.R.C.S. L.R.C.P. has been appointed Honorary Surgeon to the Nottingham Hospital for Women.

DR. LOUGHRY W. G., M.D. Lond. D.P.H. Camb. has been reappointed Medical Officer of Health for Plymouth.

Vacancies.

Further information regarding each vacancy reference should be made to the advertisement. (See Index).

TOY INFIRMARY AND DISPENSARY—Senior House Surgeon. Salary £125 per annum, with furnished apartments, board and attendance.

CHURCH DISPENSARY—Resident House Surgeon. Salary £125 a year, with furnished house, rent and taxes free, also coal, light, water and cleaning, or in lieu thereof £25 per annum.

GENERAL INFIRMARY AT GLOUCESTER AND THE GLOUCESTERSHIRE EYE INSTITUTION—House Surgeon. Salary £100 per annum, with board, lodging and washing.

HIGHWORTH AND SWINDON UNION—Medical Officer and Public Vaccinator for District No. 1 of the Union. Salary £70 per annum, with the usual extra medical fees for midwifery and surgical cases, and also vaccination fees. Apply to the Clerk of the Guardians, Office No. 6, High street Swindon.

HOSPITAL FOR WOMEN (THE LONDON SCHOOL OF GYNECOLOGY) School-square W.—Clinical Assistants.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST Brompton.—House Physicians.

INGHAM INFIRMARY South Shields.—Two House Surgeons (Senior and Junior). Salaries Senior £60 rising by instalments of £5 to £70 per annum Junior £50 per annum, each with board and residence.

LONDON HOSPITAL, Whitechapel, E.—Assistant Physician.

METROPOLITAN HOSPITAL, Kingsland road, N.E.—Dental Surgeon.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Albany Memorial) Queen-square, Bloomsbury.—Physicians for out-patients.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Albany Memorial) Queen square Bloomsbury—Registrar and Pathologist.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Albany Memorial) Queen-square, Bloomsbury—Assistant Physician.

PARISH OF ST. LEONARD Shoreditch—Second Assistant Medical Officer for the Infirmary, Hoxton street N. for six months. Salary £40 per annum, with rations, furnished apartments and washing in the Infirmary. Apply to the Medical Officer 204 Hoxton-street London, N.

POPULAR AND STEEPNEY SICK ASYLUM DISTRICT—Assistant Medical Officer for the Asylum at Bromley Middlesex, E. Salary £130 per annum, with rations, furnished apartments and washing. Apply to the Clerk to the Managers, Bromley Middlesex E.

RADCLIFFE INFIRMARY Oxford.—Surgeon, for two years. Salary £80 a year, with board, lodging and washing.

RICHMOND DISTRICT ASYLUM Dublin.—Third Assistant Medical Officer and Pathologist (unmarried).—Salary £100 per annum, with furnished apartments and other allowances, valued collectively at £99 15s. 6d.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN Waterloo-bridge road.—Resident Medical Officer. Salary £70 per annum, with board, lodging &c.

ROYAL FREE HOSPITAL Gray's-inn road.—Junior Resident Medical Officer for six months. Board, residence and washing provided.

ROYAL FREE HOSPITAL Gray's-inn-road.—Senior Resident Medical Officer for twelve months. Salary £190 per annum, with board, residence and washing.

UNIVERSITY COLLEGE, BRISTOL, MEDICAL SCHOOL—Medical Tutor. Stipend £125 per annum.

VESTRY OF FULHAM—Medical Officer of Health for the parish of Fulham. Salary £500 per annum. No further increase. Apply to the Clerk of the Vestry Town Hall Walham Green.

VICTORIA HOSPITAL FOR SICK CHILDREN Hall.—Resident Medical Officer. Salary £50 a year with board, rooms and washing.

WEST NORFOLK AND LYNN HOSPITAL, Lynn.—House Surgeon and Secretary. Salary £50 per annum, rising to £100.

YORK COUNTY HOSPITAL—Assistant House Surgeon. Salary £40 per annum with board, apartments and washing.

Births, Marriages and Deaths.

BIRTHS

BROOKS.—On March 16th, at Holywell, Oxford, the wife of Dr Brooks of a daughter.

BUTHELL.—On Jan. 23th, at Pekin, China, the wife of Dr S. W. Butshell, Physician to H.B.M.'s Legation, of a son.

CADDY.—On March 16th, at East-court gardens S.W. the wife of Duncan James Caddy M.B. of a daughter.

DEWSNAP.—On March 15th, at Gloucester road South Kensington, the wife of William Frederick Dewsnap M.R.C.S. L.R.C.P. of a daughter.

SMITH.—On March 20th at the Beeches, Shenley Herts the wife of R. V. Beatty Smyth, M.A. M.D. of a son.

MARRIAGES

GODDARD-FRY.—On March 16th, at St. Mary's, Horsell, Surrey Bertram Goddard, L.R.C.P. M.R.C.S. second son of Eugene Goddard M.D. of Highbury New Park N. to Charlotte second daughter of George Fry of Focklebrook, Chobham, Surrey.

PRICE-SMART.—On Feb. 27th, at Ramsgate John Dods Price, M.R.C.S. L.R.C.P. Lond. District Medical Officer Newington Asylum to Jessie Eleanor, only daughter of the late William Colville Smart.

DEATHS

ALLEN.—On March 17th, at his residence, Welburne Hall, Lincoln Robert Marshall Allen, F.R.C.S. Deputy Inspector-General of Army Hospitals, aged 55.

LAWRENCE.—On March 15th, at Liskeard Cornwall, John H. Lawrence M.R.C.E. aged 65.

MACKINTOSH.—On March 15th at Morden Hall, Torquay C. H. Mackintosh, M.D. St. And. M.R.C.S. Extra L.R.C.P. Lond. aged 65.

MANNING.—On March 20th, at Laverstock, Salisbury Henry Charles, eldest son of Henry John Manning, aged 24.

SIBLIT.—On March 15th at his residence The Hermitage Whitehill, Blechingley Surrey Septimus William Sibley, F.R.C.S., late of Harley street, W. aged 6.

F.B.—A fee of 5s. is charged for the insertion of Notices of Births Marriages and Deaths.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office

Lectures, original articles, and reports should be written on one side only of the paper

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor"

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Publisher"

We cannot undertake to return MSS not used

PUBLISHER'S NOTICE

IN order to facilitate the work of reference to the volumes of THE LANCET, we have arranged in the future to publish duplicate copies of the Index to each half yearly volume in a form in which they may be subsequently filed or bound together

We have had a large number of duplicate copies of the Index to the last half yearly volume printed, and those of our subscribers who may wish to be supplied with loose copies can obtain the same (without extra charge) on making application to the Publisher of THE LANCET

FOREIGN BODIES IN THE STOMACH

DRS. CAREW AND WEIR publish notes of an unusual case of foreign bodies in the stomach, in the *Canadian Practitioner* for February. The patient, a man aged twenty-three, was an inmate of the Toronto Asylum. The tableware is always counted after meals and on Oct. 27th, 1892, the knife, fork and spoon used by this patient could not be found. He said that he had swallowed them, but was not believed. The knife measured 9½ in. long, blunt-edged, with a round point, fork, 7½ in. long four-pronged, spoon, 5½ in. long—all silver plated. Next day nausea was complained of, and the foreign bodies could be distinctly felt through the abdominal wall, and a distinct clicking noise could be heard. Operation was not permitted, and the patient died of peritonitis on Jan. 27th of this year, the result of perforation of the stomach by ulceration produced by the foreign bodies. At the post-mortem examination the stomach was found to be closely adherent to the ileum and transverse colon. The handles of the knife and fork could be felt passing down through the ileum

from the point of adhesion, and their extremities lodged in the cecum the bowl of the spoon could be felt in the duodenum and its tip had caused ulceration through the anterior wall of the duodenum with a slit-like perforation into the peritoneal cavity three inches and a half from the pylorus. The point of the knife was engaged in the mucous membrane of the stomach a little below the lesser curvature in the anterior wall, and had caused some ulceration there. The points of the fork were free. The stomach showed marked chronic inflammation, also the duodenum, there was an area of ulceration of some depth in the latter where the edge of the bowl of the spoon rested, but this had not perforated like the tip. The lower end of the oesophagus showed superficial ulceration. The knife blade had been considerably eroded by the gastric juice, but the fork and spoon showed no damage beyond the loss of the silver plating. The patient complained of pain only twice and on each occasion only for a short time. The only sign locally of the peritonitis was extreme distension

"SIMULTANEOUS AFFECTION OF THE LACRYMAL AND PAROTID GLANDS"

To the Editors of THE LANCET

SIRS,—The annotation on simultaneous affection of the lacrymal and parotid glands at page 603 of THE LANCET of March 18th reminds me of a case I saw during a recent epidemic of mumps in this town. The patient, a lad about seventeen years of age suffered from mumps affecting the right parotid mainly, and in a less degree the left. In a few days after the commencement of the attack the right testicle and denly became painful and inflamed the swelling of the parotids at the same time diminishing. Three days later the mother called my attention to a small firm swelling beneath the right upper eyelid towards its outer part, which was both painful and tender and was accompanied by profuse lachrymation and some injection of the vessels of the conjunctiva. At the same visit the orchitis was found to have greatly subsided. Cold compresses to the eyelid were ordered and the swelling rapidly disappeared. The idea crossed my mind at the time that this might be a case of mumps of the lacrymal gland and I accordingly looked up such authorities as were at hand but could find no light on the matter. The rarity of the cases recorded induces me to send you this brief account.

I am, Sirs yours truly,

LEWIS E. PARKHURST, D.A., M.B., B.Ch. Oxon
Brackley, Northamptonshire March 18th, 1893.

THE CLIMATE OF AUCKLAND

A CORRESPONDENT writes to us in praise of the climate of Lake Takapuna, near Auckland, from which he has derived great advantage as a sufferer from chronic bronchitis. From a combination of geographical and other causes the health giving qualities of the locality in question are regarded by our correspondent as quite exceptional, and he regrets that no account of it has been made public in Europe. The greatest heat about 80 in the shade, is always largely modified by a constant sea breeze and a cool wind from the south blowing from the high mountains of Otago. The rainfall is about forty nine inches and very evenly distributed during the year. The humidity of the region is so tempered that sufferers from bronchial affections are able to be out of doors almost all the year round. Frost is but rarely seen, the orange, the lemon and the guava tree flourish here in the open. Other advantages of the climate are enumerated and extolled by our correspondent, to which we have no space here to refer

Mr F. Sykes is thanked for his kind offer

GLYCERINE SUPPOSITORIES.

To the Editors of THE LANCET

SIRS,—The suppositories of glycerine mentioned by me in my recent article in THE LANCET can be procured at Mr Morgan Richards, 40 Holborn Viaduct London. They contain 95 per cent of glycerine, and their price is, I believe, 1s 9d. per dozen. They are made in two sizes, for children and adults. Would Mr Marshall of Mitcham and others who have written to me about these suppositories be kind enough to take this letter as an answer to their questions?

I am, Sirs, yours faithfully,

Bristol, March 18th, 1893. JAMES D. STAPLE, M.R.C.S. &c.

STATISTICS OF POPULATION

To the Editors of THE LANCET

SIRS,—Can any of the readers of THE LANCET inform me whether there are any statistics or other reliable information published on the following points? 1 The number of children born to each married couple in England and Wales, if possible distinguishing (a) the upper and middle classes (b) the sex of the population 2 Out of the children born how many attain the age of twenty one years?

I am, Sirs, yours truly,

Ladbroke-grove, W., March 21st, 1893 J. C. POLLOCK MUR.

CHOLERA IN UPPER ITALY

CHOLERA seems to have 'cast a shadow before' in the sub-Alpine commune of Entraque a neighbourhood numbering about 260 inhabitants some fifteen miles from Cuneo. The facts so far as ascertained by our Rome correspondent are the following. On the 7th inst. an Italian workman, aged forty, of weakly constitution, had crossed the frontier from France and fell ill at Entraque. In a few hours, during which he was attended by the local practitioner he died of what appeared to be distinctly pronounced cholera morbus. Thereupon the prefect, the Commendatore Alfazio sent for Dr Ambrosi the medico provinciale who immediately took all steps for the isolation of the malady and proceeded to a necropsy which confirmed the suspicions of the local attendant. The dejections carefully preserved, were removed for analysis; the results of which are not yet made public. The Home Office also received telegraphic notice of the case and the most rigorous surveillance was at once enforced at the frontier the French side of which is said to be ill provided from a hygienic point of view, and to be never without high rates of sickness and mortality. Unfortunately the case of the workman has not been singular. His mother in law a woman of seventy who nursed him was also taken ill, and, after a brief course of precisely the same symptoms died on the 12th. Dr Ambrosi having returned from an interview with the Commendatore Alfazio at Cuneo is redoubling his precautions at Entraque whilst strong detachments of carabineers and of the neighbouring Alpine regiments are vigilantly safeguarding all the approaches from France to Italy. Inspection and disinfection are practised on the minutest and most rigorous scale on all arrivals and none are allowed to pass without a medical certificate of ascertained fitness to do so. At Entraque itself the Church of Sant Antonio has been transformed into a lazaretto and no measures are spared to protect the country from such a visitation as that of 1834 which though carefully 'hushed up' was exceptionally severe as the Piedmontese and Liguian populations have every reason to remember."

IS THE "USUAL BOND" BINDING ON UNQUALIFIED ASSISTANTS?

To the Editors of THE LANCET.

SIRS.—Four years ago I was dispenser and did visiting for a medical gentleman, and at that time I had not done any hospital work, but I attended some of the College lectures. I was asked to sign a document which was to the effect that I would not practise within a radius of three miles from the residence of my employer. I am now fully qualified and registered, and I wish to ask you if such a document as the one I signed being then unqualified and it being now four years since I signed it no time having been specified therein prevents me from commencing practice on my own account in that town? Or is such a document an everlasting bar to my practising there?

I am, Sirs yours faithfully

March 21st 1893. L.R.C.P. L.R.C.S. ED. &C.

* It is not possible to give a positive opinion without seeing the agreement, which we are inclined to think may be valid. Our correspondent should consult a solicitor.—ED. L.

THE PUBLICATION OF THE DETAILED CENSUS REPORT

A CORRESPONDENT asks us for information as to the probable date upon which the public will be able to know the result of the Census which was taken two years ago. Volumes 1 and 2 of the Detailed Census Report will we are informed probably be presented to Parliament in the course of next month. Volume 3 (dealing with ages, birthplaces, occupations and infirmities) about midsummer and Volume 4 (containing the general report and index) early in the autumn. We may point out that the Preliminary Census Report issued in July 1891 gave the unreviewed results of the Census in counties, registration areas municipal boroughs and all other sanitary districts and in all Parliamentary areas.

MENTAL SCIENCE AT THE UNIVERSITY OF LONDON

To the Editors of THE LANCET.

SIRS.—I should esteem it a great favour if you would give me some idea of the best books to read for the examination in mental and moral science in the Final M.D. examination at the University of London. So far as I can learn, the candidates always seem to be very much troubled in answering the questions on account of their not knowing what to read.

I remain, Sirs, yours truly
March 23rd 1893. V.B.

Agent for the Advertisement Department in France—J. ASTIER, 66, Rue Cassini, Paris.

REPORT OF THE LANCET COMMISSION

APPOINTED TO INVESTIGATE THE SUBJECT OF THE

ADMINISTRATION OF CHLOROFORM

AND OTHER ANÆSTHETICS

FROM A CLINICAL STANDPOINT

As mentioned in the introductory portion of this report, the basis of the statistics set forth is the series of cases, a portion of which we publish, with as full particulars as it is possible to produce in tabular form. The cases are those in which death has occurred when chloroform was being administered and when the death was apparently due to the direct influence of the drug and was so regarded by those who reported the occurrence. It has been thought advisable to divide these cases into three Series. In the first series (Series A) the deaths include those which occurred between the years 1848 and 1860. This series corresponds with the record of fatalities reported by the Special Committee of the Royal Medical Chirurgical Society published in vol. xxix of the Second Series of their Transactions in 1864 (p. 323 *et seq.*). It was, however, found necessary, in order to render this series more complete, to examine the journals and other published records of cases and to collate the facts so obtained with those furnished by the Royal Medical and Chirurgical Society's Transactions. Special assistance was obtained by the examination of Dr. Snow's volume, which, besides giving very full records of cases, furnished incisive criticisms and comments which suggested a further search for information. The second series (Series B) comprises the record of cases obtained from published accounts of fatalities which occurred between 1860 and 1891. The sources of information for these were the current medical literature and records afforded us in the shape of answers sent in to us in reply to our circular by medical practitioners both in the United Kingdom and abroad. The utmost attention has been paid to tabulating the records and in most instances several accounts of each fatality have been consulted and the essential particulars taken from them so as to form as full and connected a narrative as possible. The amount of information to be obtained varies very considerably, it being full to redundancy in some instances but most meagre in others. It has, however, been thought advisable to maintain the sequence by inserting the cases even when only the mere fact of the death has been notified. In the instances in which the deaths were reported to us by practitioners we have regarded the communication as a private one, in accordance with the terms of our forms, and have omitted from our published report the name of the patient and that of the medical man. In the third series (Series C) are included (1) the cases of fatalities which had occurred in private practice under chloroform reported by medical men on the smaller form sent out with THE LANCET inquiry, (2) similar cases supplied by hospital authorities on the larger form.

The first column in the tabular matter which we publish contains a number which refers to the original lists, thus affording a means of substantiating the authenticity of the record. The first series comprises 86 cases, the second series 539 and the third 27. The headings "Age" in the second and "Sex" in the third column need no special comment.

In the fourth column the nature of the operation and the duration of the period of administration of the chloroform are given. We have already pointed out the importance of affording due consideration to possible factors in determining a fatal result to chloroformisation, instancing the assumed danger of some operations when of a nature to give rise

especially to shock. The importance of considering the duration of the narcosis is evident when we remember that cooling of the patient's body, after effects such as sickness, the phenomena which many authorities, grouping together under the term "shock," believe to be the direct result of the action of the anæsthetic, are proportional to the time the patient is exposed to the influence of the chloroform. The duration is taken as representing the period of time between the commencement of the inhalation until the death of the patient, or, perhaps more correctly, until the commencement of measures adopted with a view of resuscitating the patient.

The next column is occupied with information concerning the nature of the anæsthetic and the method of employing it. Here we regret to have to draw attention to the loose way in which the "method" employed has been, as a rule, described. A detailed and exact definition of the method employed in every case of death under chloroform would probably lead to valuable criticism from those constantly engaged in the use of anæsthetics, and errors or slight inaccuracies of technique might be pointed out which would possibly save a repetition of errors sometimes immediately responsible for the fatality.

In the sixth column the question of pulse (P) and respiration (R) is considered with regard to which failed first. Thus, when the reports furnished to us state that the respiration failed before the pulse, this is notified in the column by the letter R. When the pulse is said to have ceased before respiration, it is represented by P, whilst when respiration and pulse are reported as stopping simultaneously, it is explained by the sign R and P. When doubt existed as to which failed first, a note of interrogation is used or placed before the letter P or R, according as the report said "probably" the pulse or the respiration failed first. Full allowance has been made for the difficulty of obtaining accurate information on this point, in the excitement of an impending death under chloroform, but the large number of cases examined possibly helps to eliminate errors of observation. Again, the liability to error most likely tells as much against one set of observations as against the other.

In the column dealing with the symptoms occurring under the anæsthetic as full but succinct an account of the whole case is given as the material at hand permitted.

In the eighth column the assigned cause of death is recorded and an attempt made to inquire into the indirect or adjuvant causes. In this column, also, is included a very brief account of the post-mortem appearances when a necropsy took place and was reported to us. Although these notes are very short it is believed that they include all the salient points. In some cases it will be noticed that the estimation formed of the patient's condition before the anæsthetic is in marked contrast with what the necropsy revealed.

In the ninth column, under the heading of "Remarks," are included facts which bear upon the general state of health of the patient at the time of the administration which might indicate a predisposing cause for his death under the anæsthetic. It is not for a moment contended that these records supply sufficient data for complete answers to the problems which the subject presents, but it is hoped that they may assist in obtaining a more thorough and intimate knowledge of the subject. When the full records have been published and the other anæsthetics have been considered in a similar way, it is proposed to offer some further remarks in which the various agents employed in producing anæsthesia and their effects will be compared.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Office letters addressed to initials only

An original and novel feature of THE LANCET General Advertiser is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 65, Rue Caumartin, Paris.

REPORT OF THE LANCET COMMISSION

APPOINTED TO INVESTIGATE THE SUBJECT OF THE

ADMINISTRATION OF CHLOROFORM

AND OTHER ANÆSTHETICS

FROM A CLINICAL STANDPOINT

As mentioned in the introductory portion of this report, the basis of the statistics set forth is the series of cases, a portion of which we publish, with as full particulars as it is possible to produce in tabular form. The cases are those in which death has occurred when chloroform was being administered and when the death was apparently due to the direct influence of the drug and was so regarded by those who reported the occurrence. It has been thought advisable to divide these cases into three Series. In the first series (Series A) the deaths include those which occurred between the years 1848 and 1860. This series corresponds with the record of fatalities reported by the Special Committee of the Royal Medical Chirurgical Society published in vol. *xxix.* the Second Series of their Transactions in 1864 (p. 323 *seq.*) It was, however, found necessary, in order to render this series more complete, to examine the journals and other published records of cases and to collate the facts obtained with those furnished by the Royal Medical and Chirurgical Society's Transactions. Special assistance was obtained by the examination of Dr. Snow's volume, which, besides giving very full records of cases, furnished valuable criticisms and comments which suggested a further search for information. The second series (Series B) comprises the record of cases obtained from published accounts of fatalities which occurred between 1860 and 1891. The sources of information for these were the current medical literature and records afforded us in the shape of answers sent to us in reply to our circular by medical practitioners both in the United Kingdom and abroad. The utmost attention has been paid to tabulating the records and in most instances several accounts of each fatality have been consulted and the essential particulars taken from them so as to form as full and connected a narrative as possible. The amount of information to be obtained varies very considerably, being full to redundancy in some instances, but most meagre in others. It has, however, been thought advisable to maintain the sequence by inserting the cases even when only the mere fact of the death has been notified. In the instances in which the deaths were reported to us by practitioners we have regarded the communication as a private one, in accordance with the terms of our forms, and have omitted from our published report the name of the patient and that of the medical man. In the third series (Series C) are included (1) the cases of fatalities which occurred in private practice under chloroform reported by medical men on the smaller form sent out with THE LANCET inquiry, (2) similar cases supplied by hospital authorities on the larger form.

The first column in the tabular matter which we publish contains a number which refers to the original lists, thus affording a means of substantiating the authenticity of the record. The first series comprises 86 cases, the second series 589 and the third 27. The headings "Age" in the second and "Sex" in the third column need no special comment. In the fourth column the nature of the operation and the duration of the period of administration of the chloroform are given. We have already pointed out the importance of affording due consideration to possible factors in determining a fatal result to chloroformisation, instancing the assumed danger of some operations when of a nature to give rise

especially to shock. The importance of considering the duration of the narcosis is evident when we remember that cooling of the patient's body, after effects such as sickness, the phenomena which many authorities, grouping together under the term "shock," believe to be the direct result of the action of the anæsthetic, are proportional to the time the patient is exposed to the influence of the chloroform. The duration is taken as representing the period of time between the commencement of the inhalation until the death of the patient, or, perhaps more correctly, until the commencement of measures adopted with a view of resuscitating the patient.

The next column is occupied with information concerning the nature of the anæsthetic and the method of employing it. Here we regret to have to draw attention to the loose way in which the "method" employed has been, as a rule, described. A detailed and exact definition of the method employed in every case of death under chloroform would probably lead to valuable criticism from those constantly engaged in the use of anæsthetics, and errors or slight inaccuracies of technique might be pointed out which would possibly save a repetition of errors sometimes immediately responsible for the fatality.

In the sixth column the question of pulse (P) and respiration (R) is considered with regard to which failed first. Thus, when the reports furnished to us state that the respiration failed before the pulse, this is notified in the column by the letter R. When the pulse is said to have ceased before respiration, it is represented by P, whilst when respiration and pulse are reported as stopping simultaneously, it is explained by the sign R and P. When doubt existed as to which failed first, a note of interrogation is used or placed before the letter P or R, according as the report said "probably" the pulse or the respiration failed first. Full allowance has been made for the difficulty of obtaining accurate information on this point, in the excitement of an impending death under chloroform, but the large number of cases examined possibly helps to eliminate errors of observation. Again, the liability to error most likely tells as much against one set of observations as against the other.

In the column dealing with the symptoms occurring under the anæsthetic as full but succinct an account of the whole case is given as the material at hand permitted.

In the eighth column the assigned cause of death is recorded and an attempt made to inquire into the indirect or adjuvant causes. In this column also, is included a very brief account of the post-mortem appearances when a necropsy took place and was reported to us. Although these notes are very short it is believed that they include all the salient points. In some cases it will be noticed that the estimation formed of the patient's condition before the anæsthetic is in marked contrast with what the necropsy revealed.

In the ninth column, under the heading of "Remarks," are included facts which bear upon the general state of health of the patient at the time of the administration which might indicate a predisposing cause for his death under the anæsthetic. It is not for a moment contended that these records supply sufficient data for complete answers to the problems which the subject presents, but it is hoped that they may assist in obtaining a more thorough and intimate knowledge of the subject. When the full records have been published and the other anæsthetics have been considered in a similar way, it is proposed to offer some further remarks in which the various agents employed in producing anæsthesia and their effects will be compared.

DEATHS UNDER CHLOROFORM

CASES FROM ROYAL MEDICAL CHIRURGICAL SOCIETY'S REPORT BETWEEN 1848 AND 1860

1 Reference.	2 Age	3 Sex	4 Operation and duration of administration.	5 Method of administration	6 P or R	7 Symptoms occurring under anæsthetic.	8 Assigned cause of death.	9 Remarks.
1	15	F	Removal of too nail (½ minute)	Handkerchief 1 dr		Anæsthesia incomplete. Became blanched spluttered as in epilepsy never rallied.	P M Stomach was distended with food. 'Syncope' (Snow)	Snow believed induction of anæsthesia was in this case too rapid.
2	36	F	Extraction of teeth (1 minute)	Dr Morton's Ether Inhaler ^a Large quantity	P	Operation nearly completed Arms became rigid P ceased after being feeble R ceased about same time. Became livid Death in 8 minutes	Syncope. P M. Nothing very remarkable save fluidity of blood.	Remarks as in previous case.
3	M		Fistula in ano (1 minute)	Towel or handkerchief. ½ dr	P	Anæsthesia incomplete (?). Showed slight symptoms of feeling pain. The P which was full and natural, sank. Death in 1 minute.	"Overdose" in way given (Snow) P.M. Heart enlarged, pale and soft.	Had had chloroform before. Was placed on his side.
4	F		Opening a sinus in thigh.	Handkerchief, 3 to 4 dr		Put up her hand and said 'I choke' Face immediately became pale breathing embarrassed Foamed at mouth Anæsthesia incomplete Death in 1 minute, probably before operation commenced	P.M. Heart pale and irritable.	Among measures adopted for resuscitation was forcible inflation of lungs this caused permanent distension of alveoli.
5	F		Amputation of middle finger	Handkerchief, 1 dr	P & R	"Coughed a little then gave a few convulsive movements" Anæsthesia incomplete. Death probably before operation commenced, probably in 1 or 2 minutes Death in 5 minutes.		
6	22	M	Cautery to wrist.	Apparatus.				
7	34	M	Amputation at hip for bullet wound.	Apparatus.		Breathing became stertorous and then very feeble countenance livid eyes turned upwards; P had ceased. Artificial R seemed to revive him and I was again felt, he relaxed however, and died Death on re application of CHCl ₃ , when sensibility was returning		
8	18	M	Extraction of teeth	In ether apparatus		Hands fell down and head fell on chest Artificial R but no recovery Incomplete anæsthesia. Operation not commenced Operation not commenced.		
9	F	M	Operation on great toe					
10	17	M	Phimosis and for hemorrhoids.	Napkin. 3 dr	P	Operation completed. Complete anæsthesia. Face and neck became livid eyes turned upwards P imperceptible at wrist and whole body relaxed After 2 or 3 gasps he ceased to breathe Death in 10 minutes	Syncope. P M Heart large and flabby lungs a good deal "congested"	Had inhaled CHCl ₃ before. Some of same chloroform had been used for another patient with out bad effects.
11	17	M	Amputation of finger, 5 minutes.	Dropped on gauze laid on face, 2 dr	P	He struggled for a moment then after a quarter of a minute the P ceased to beat countenance altered Action of heart had ceased and the sounds could not be heard. R. still continued, but became irregular weak and slow and at length ceased completely in space of ½ minute. At tempts made to restore R, and in 2 minutes again commenced but I did not return Death in 6 minutes, during stage of excitement.	Syncope (Snow) P M Vena Cava overfull of black blood.	Snow thinks an overdose was taken when the patient struggled.
12	36	M	Amputation of toe.	Handkerchief, ½ oz.		Anæsthesia complete. At close of operation no blood escaped when pressure was removed from arteries patient was in fact dying and in a short time expired A few inspirations were noticed after I had ceased at wrist.	P M Some venous congestion of lungs, heart flabby	Death probably due to way the CHCl ₃ was given (Snow)
13	F		Extraction of tooth.	Handkerchief	P	As she did not become insensible more CHCl ₃ was placed in handkerchief She drew one deep inspiration countenance immediately became pallid, dilatation of pupils, convulsive rolling of eyes, no P could be felt.	"Paralysis of heart by overdose.	The inspiration at the moment the fresh supply of chloroform was given probably induced intaking of a lethal dose (Snow) Pt. was sitting
14	48	M	Removal of too nail.	Inhaler About ½ dr	P & R	Anæsthesia complete Continued insensible after operation face becoming dark P small quick R laborious. After struggling for a minute became still R continued a few seconds after P ceased. Artificial R. produced no effect.	Probably asphyxia (Snow)	
15	F		Excision of eye ball.	Sponge. Small dose.	P	Probably fully under Died suddenly during operation.	Syncope.	"Vapour not sufficiently diluted" (Snow)

^a Consists of glass globe containing a sponge on which the chloroform was poured to saturation The globe was 4½ inches across, and the sponge filled one third of it.

DEATHS UNDER CHLOROFORM.

CASES FROM ROYAL MEDICAL CHIRURGICAL SOCIETY'S REPORT BETWEEN 1848 AND 1860 (continued)

1	2	3	4	5	6	7	8	9
No. of cases.	Sex.	Age.	Operation and duration of administration.	Method of administration.	P or R.	Symptoms occurring under anæsthetic.	Assigned cause of death.	Remarks.
15	F		Extraction of tooth.	Sponge and napkin.	* P	Died suddenly stretching herself out and frothing at the mouth at moment of death, countenance at same time becoming livid.	Syncope.	Operation seems to have been attempted several times at intervals unsuccessfully. Died when inhaling CHCl_3 for 6th time.
17	M			Sponge, 1 dr.	* R.	During stage of excitement, made a strenuous inspiration and this occurred several times until at length R. ceased entirely not. (No report of P.) Operation probably not commenced.	"Probably syncope."	
18	F		Amputation of finger.	Handkerchief, 1 dr		Operation probably completed. After CHCl_3 was discontinued face turned pale, and P and R. ceased.	Syncope. P.M. showed Pt. to be emphysematous.	
19	M		On testicle.	Cotton and folded towel. About $2\frac{1}{2}$ dr	P	Some struggling on breathing fresh CHCl_3 . Towel removed, but patient not being insensible, again applied. After a few inspirations P. ceased, face turned pale breathing slow and gradually ceased. Death in 5 minutes. Operation not commenced.	Cardiac syncope. Breathing returned for a time after the employment of artificial respiration. P.M. showed old standing disease of membranes of brain.	
20	M		Sounding for stone.	On lint.	P	Insensible, moaning. Countenance livid, eye vacant. Heart pulsation ceased. Made one deep gasp and was to all appearance dead. Artificial R. no result.	Syncope.	
21	M		Amputation of portion of hand.	Inhaler then napkin.	P	During operation hæmorrhage suddenly ceased, and he expired.	Syncope. P.M. Heart flabby some congestion of brain membranes.	See Snow p. 132.
22	M		Amputation below knee for scrofulous disease of ankle.	Lint and towel with sponge, laid on face. About $1\frac{1}{2}$ dr		Slight convulsive movement of eyelids, froth at mouth and he was dead. Operation not commenced. Death in about 1 minute.	Syncope—From commencement of administration to death only one minute elapsed.	Patient greatly debilitated.
23	M		On penis.	Chloroform, 1 dr		Died suddenly	Syncope.	
24	M		Extraction of teeth.	Handkerchief.		After extraction of some teeth she died suddenly in less than 1 minute from commencement of the inhalation	Syncope—Pt. was emphysematous.	The administrator was prosecuted for homicide but acquitted.
25	M		Removal of testicle.	Linen cloth. About $1\frac{1}{2}$ dr	P & R.	Fully under influence. During operation hæmorrhage from artery suddenly ceased. R. ceased almost instantaneously with heart's action, but one or two sigh like inspirations followed. With artificial R. there were several attempts at a natural R. Death after more than 7 minutes.	* Syncope (Snow) P.M. Fulness of veins—fibrinous clot in pulmonary artery	
26	F		Removal of impacted foreskin. (Cancer of urethra.)	Probably handkerchief, $10\frac{1}{2}$ dr		On completing operation the surgeon found that she had ceased to breathe. She was fully under anæsthetic. Death in 8 or 9 minutes.	* Syncope. Symptoms do not appear to have been observed.	
27	M		Ligature of arteries, aneurism in leg by anastomosis.	Apparatus.		Operation commenced. P. suddenly ceased as soon as skin incision was made. CHCl_3 removed but in a few seconds patient had ceased to breathe. With artificial R. the act of R. was performed several times and the circulation was thought to be returning but this was only due to appearance of face no pulse returned, but he quickly relapsed and died. Death in 5-10 minutes.	Syncope P.M. Venous engorgement.	
28	F		Extraction of tooth.	Sponge and handkerchief, 25 drops.		Only 4 or 5 inspirations. Operation not commenced. On being asked a question, answered in a thick and trembling voice. At same time stretched out her limbs face became bluish eyes haggard head and arms fell she was dead.	Syncope.	Was in sitting posture.
29	M		Lithotripsy	Snow's Inhaler.		Operation commenced, fully under Fresh CHCl_3 given as signs of returning consciousness appeared. Appeared to hold his breath. P. had then ceased, the heart sounds were still heard feebly. Made several further inspirations and then ceased to breathe. Artificial R. produced no result.		
30	M		Fistula in ano.	Handkerchief. About 1 dr		Not fully under operation not commenced. On applying fresh CHCl_3 he spluttered at mouth. CHCl_3 was removed, but he suddenly expired. Death in about 1 minute.	Syncope.	

DEATHS UNDER CHLOROFORM

CASES FROM ROYAL MEDICAL AND CHIRURGICAL SOCIETY'S REPORT BETWEEN 1848 AND 1860 (continued)

1 Reference.	2 Age.	3 Sex.	4 Operation and duration of administration.	5 Method of administration.	6 P or R	7 Symptoms occurring under anæsthetic.	8 Assigned cause of death.	9 Remarks.
31		M	Application of potassa fusa to ulcers.			Fully under When nearly completing operation a sort of catch in breathing on looking at him, mouth and eyes open and turned upwards breathing irregular face pale, and pupils dilated Artificial R. had no effect. "In a few minutes the man died	Probably syncope.	
32		M	Removal of malignant tumour of the thigh (12 minutes)	Inhaler		Fully under CHCl ₃ acted slowly During operation breathing became slow seemed to be sinking fast, gave one strong gasp, and then died.	Probably syncope.	
33	28	F	Application of nitric acid to sloughing ulcers.	Lint.		Operation not commenced During stage of excitement, a partial relaxation of the limbs took place, became insensible and pulseless.	Syncope.	
34		F	Tumour of face.	Compress.		Stage of excitement. During operation had cough; made a deep inspiration, then a convulsive movement of face and hand P and heart had ceased.		
35		M	For hemorrhoids.			Fully under Operation not commenced R. became embarrassed there was trismus; then the movements of heart ceased With insufflation, and then with electricity he breathed irregularly for 20 minutes There was however, no evidence of restored action of the heart. Death in less than 5 minutes		Patient suffering aneurism of aorta.
36	26	M	Removal of tumour near lip	Sponge. 5 dr		Fully under Operation commenced Became pale, R. suspended, sank into state of complete collapse Artificial R. produced no effect Death in about 4 minutes.	Syncope.	
37	43	M	Perineal section	Handkerchief About 1 oz	P	Fully under Operation not commenced Had slight convulsion; rallied and continued CHCl ₃ ; I became weak and ceased. Breathing did not cease before I Artificial R. restored a few natural R's but this did not continue	Syncope	
38	40	F	Strangulated hernia.	Lint. Less than 2 dr		Operation not commenced Struggled much commenced to breathe with loud rough stertor I was gone gave several inspirations, then ceased With artificial R. and galvanism gasped about 3 times After this no further signs of life	"Simultaneous deep coma and cardiac syncope"	
39	22	F	Application of actual cautery to canceroid sore	Inhaler About 2½ dr		Fully under Operation not commenced P became extremely weak and fluttering countenance dusky R. at long intervals with slight catching efforts All efforts at R. ceased about 2 minutes after 1st indication of failure I, however, as a very feeble flutter was felt occasionally for at least 2 minutes later	Syncope	
40	19	M	Extension of ankylosed knee.	Inhaler Chloroform, 1 dr		Probably not under influence Operation not commenced P became feeble and undulating trismus occurred R. became irregular face livid foamed at mouth Only once made feeble attempt at R. Death in less than 1 minute	Syncope.	
41	18	F	Lipoma on back.	1 dr		Fully under Operation commenced Fell suddenly forward on chest. Attempts made to restore her but in a few minutes it became evident that she was dead		
42	59	F	Attempt to reduce dislocation at shoulder	Sponge. 2 drs.	F R.	Respiration became stertorous, and immediately afterwards the pulse, which had hitherto continued pretty firm, became imperceptible respiration ceasing at same time. 'Galvanism applied some convulsive efforts of respiratory muscles, but no further sign of life about 6 minutes. Not commenced.	'Deep coma and cardiac syncope'	
43	45	F	Removal of cancer of breast.		P	After inhaling with little effect for forty minutes the chloroform took effect but the countenance changed and pulse ceased, after a few short laboured inspirations life became extinct Fully under More than 40 minutes	Cardiac syncope	
44	40	F	Removal of uterine polypus	Lint.	P	Pulse ceased to beat face was extremely pale; a slow respiration still continued but soon ceased. Fully under Time not stated.	Cardiac syncope.	

DEATHS UNDER CHLOROFORM

CASES FROM ROYAL MEDICAL CHIRURGICAL SOCIETY'S REPORT BETWEEN 1848 AND 1860 (continued)

1	2	3	4	5	6	7	8	9
Reference	Age	Sex	Operation and duration of administration.	Method of administration.	P or R.	Symptoms occurring under anæsthetic.	Assigned cause of death.	Remarks
46	18	M	Operation for phimosia.	(Not covering nostrils) 2 drs	P	Pulse suddenly failed, became imperceptible, countenance assumed a pale, leaden hue. With stimulus of cold water after three or four minutes, pulse again felt, and spontaneous respiration renewed. This improvement continued for ten minutes then pulse and respiration ceased together. Artificial respiration produced no effect. Complete insensibility. About 6 minutes.	Cardiac syncope.	
48	39	F	Removal of tumour of breast.	Rather more than 1 dr		Breathing suddenly ceased; became deadly pale. No pulse could be felt there were then two sighing efforts at respiration. Artificial respiration commenced within one minute, without effect. Commencing to inhale. One minute and a half.		
47	M		Reduction of dislocation of hip.	Apparatus (which mixed air with the chloroform).	P	Pulse ceased, became pale; the respiration continued but slow and irregular. Friction, ammonia, artificial respiration, the arms were raised and some pulsations were again felt. Appeared to answer questions but then fell back again into a state of syncope. Reduction effected. Complete anæsthesia. A few minutes.	Syncope	
48	13	M	Cleft palate	A compress held two centimetres in front of mouth	P	Pulse ceased, strange expression of face. With artificial respiration and cautery there were two or three efforts at respiration. Fully under during the operation.	Syncope.	
49	6	M	Amputation in thigh 13-14 n. n.	Snow's Inhaler 3 drs.	P & R	Pulse which was full and steady gave a few rapid irregular beats, then ceased, respiration ceased simultaneously, face became pallid and deathlike. Artificial respiration was followed by slight effort at inspiration. Stage of excitement 14 minutes.	Syncope.	
50	39	M	Introduction of catheter	Lint.	R.	Began to snore, then a long interval, breathing became feeble and was ceasing; artificial respiration then used, and after a few minutes it then recovered but again ceased. The pulse had continued to beat some little time after these symptoms, and after cessation of respiration. Fully under.	"Deep coma apnoea, syncope	
51	56	F	Amputation of leg 3 minutes.	Lint, in oil silk. 2 drs	P	Pulse suddenly ceased in femoral then several respirations which ceased but were renewed slightly with artificial respiration. Fully under. About 3 minutes.	Syncope.	
52	40	M	Excision of eyeball 5 minutes.	Snow's Inhaler	P & R	Respiration became feeble and sighing. With artificial respiration there was occasional breathing but this presently ceased. Pulse, when felt for after spasm subsided, was absent. Operation not commenced. Death during stage of excitement.	Syncope.	
53	29	F	For relief of facial neuralgia. A few seconds.	An Inhaler $\frac{1}{2}$ dr		Having inhaled 20 minims, she begged for more, began to inhale eagerly, gave a sudden start as if taken in some kind of fit. No further sign of life. Not fully under.	Syncope.	Was sitting up and inhaled 2 or 3 times before.
54	36	F	Tooth extracted? A few seconds.	Handkerchief. About $1\frac{1}{2}$ dr	P & R	Spoke and said "I am not over yet and immediately while yet speaking she gave a convulsive start, and with a stertorous inspiration and with the eyes and mouth open, sank to the floor. Artificial respiration was employed and after a short time there were a few spontaneous inspirations and it is said the pulse could be perceived at the wrist. Quite conscious. Death in about a minute. Operation not commenced.	Syncope.	Sitting posture. Had inhaled chloroform 4 times previously.
55	30	M	Removal of necrosed bone from finger 3-4 minutes.	Sponge in lint.		Raised hands and trembled. Kept spitting at the lint, appeared about to vomit. Suddenly he was violently convulsed, as if in an epileptic fit. The chloroform was at once discontinued and he was laid in a semi horizontal posture. The convulsion lasted only a few seconds. He began to breathe with effort, and to gasp irregularly. His pulse was almost imperceptible and intermittent. With artificial respiration he rallied and breathed without assistance. In a few seconds he relapsed and could not be recovered. Not fully under. Operation not commenced.	Deep coma and cardiac syncope	Sitting posture

DEATHS UNDER CHLOROFORM
CASES FROM ROYAL MEDICAL CHIRURGICAL SOCIETY'S REPORT BETWEEN 1848 AND 1860 (continued)

1 Reference.	2 Age.	3 Sex.	4 Operation and duration of administration.	5 Method of administration.	6 P or R.	7 Symptoms occurring under anæsthetic.	8 Assigned cause of death.	9 Remarks.
56	8	M	Excision of scapula. A few minutes.	First an inhaler, then lint.	P	After making one long, deep inspiration (from lint) appeared to pass into a deep sleep. A few seconds later, pulse began to beat very quickly, then ceased for two or three seconds, then beat rapidly several times and ceased. He continued to breathe for at least a minute longer. Respiration was ceasing, but continued, with cold water &c, for two or three minutes. Brandy poured into the mouth passed into œsophagus, but no effort to swallow. Artificial respiration produced some efforts at inspiration; but he did not rally. Under influence. Operation not commenced. Death in a few minutes.	Syncope.	
57	35	M	Amputation of thigh. A few minutes.	Lint not a large quantity.	P	On raising eyelid it remained retracted, eyes slightly turned up. No pulsation in temporal or wrist. The respirations had almost ceased. With cold water &c., respiration became better, in about 2 minutes a pulse was felt at the wrist. This continued with good respirations, 2 or 3 minutes. The pulse then failed, and then the respirations. Artificial respiration produced no effect. Fully under. Death in a few minutes. 10 minutes from the time on table till death but had inhaled in the ward 3 or 4 minutes before. Operation not commenced.	Syncope.	
58	17	F	Application of nitric acid to sores.	Snow's inhaler 1 dr.		The operation being completed moved as though recovering and was left. A few minutes later being noticed to be pale, was found pulseless and dead. Artificial respiration produced no effect. Fully under. Operation completed. Death in few minutes.	? Syncope.	
59	49	M	Excision of elbow joint. Two minutes.	Hollow sponge. About 1 dr.	P	Gasping respiration followed by slow convulsive movement of limbs. The pupils became dilated, and the pulse stopped. Not under influence. Operation not commenced. Death in about 2 minutes. Died suddenly.	? Syncope.	Sitting posture.
60		M	Extraction of teeth.				? Syncope.	Intemperate.
61	23	M	Plastic operation on forehead.	6 drs.		Great excitement with tossing about of limbs, followed by sudden collapse. Not fully under influence. Operation not commenced.	? Syncope.	
62	30	M	Removal of finger.	About 2 drs. used given in 30 minute doses.	R.	The chloroform caused a little cough at first which soon ceased and the stage of excitement set in. When nearly insensible he did not breathe freely and there was spasmodic action of the larynx, as if from repeated swallowing of saliva. Chloroform was discontinued and respiration had entirely ceased. No pulse could be felt. Artificial respiration and other means produced no effect. The heart's action continued for some time after the breathing and pulse had failed. Anæsthesia nearly complete. Operation not commenced.	? Asphyxia. P M. Frothy mucus throughout air passages. Lungs healthy. Heart substance healthy and firm, a little fat on external surface of left ventricle. Valves natural.	
63	11	M	To examine an injury of the foot, of some weeks' standing.	Cotton handkerchief.	P	The boy was much frightened and breathed irregularly at first. Fresh chloroform was added, and after 6 or 8 inspirations he became insensible. The handkerchief was given to the mother to hold and the examination of the foot commenced. Stertor set in, and the chloroform was discontinued. Pulse became imperceptible. Lips livid. Artificial respiration produced a few short inspiratory efforts. No return of pulse. Extreme insensibility. Death in ten minutes from the commencement of inhalation.	? Overdose leading to paralysis of respiratory and cardiac centres.	
44	40	F	ut					

DEATHS UNDER CHLOROFORM

CASES FROM ROYAL MEDICAL CHIRURGICAL SOCIETY'S REPORT BETWEEN 1848 AND 1860 (continued)

1 Reference	2 Age	3 Sex	4 Operation and duration of administration.	5 Method of administration.	6 P or R.	7 Symptoms occurring under anæsthetic.	8 Assigned cause of death	9 Remarks.
64		F	Extraction of tooth.	Handkerchief.		'Seized with alarming symptoms. Operation completed.		Sitting posture
65	8	M	Operation for strabismus.	Piece of lint. About 1½ dr used at 3 applications.	P	He flinched as the operation was commenced. More chloroform poured on lint. Face instantly became pale and pulse ceased. Up till this had been quite regular, 80 per minute. Incomplete anæsthesia. Death in ten minutes.	? Syncope.	
66	45	F		Handkerchief				
67	43	M	For reduction of subcoracoid clava dislocation.	Piece of linen rolled into cone. From 4-5 drs. used.	P	Excitement followed the fresh application of chloroform but soon passed off. Operation completed. Pulse and respiration regular when pulse suddenly stopped a few rapid, deep inspirations continued. Anæsthesia. Chloroform had been removed and remarks were being made by operator. Reduction effected.	? Syncope.	
68	7½	F	Foreble straightening of hip-joint.	Sponge. About 1 dr	P	Resisted when touched. On second attempt crying and struggling ceased. Circulation had stopped. Lungs continued to act for a few respirations. Incomplete anæsthesia. Operation not commenced.	? Syncope.	
69	16	F	Operation for strabismus.	Piece of folded linen.	P	She gave a shrick and became insensible. The operation was commenced. Face became livid. Pulse could not be felt; slight inspiratory efforts at intervals for a long time and movement of nostrils, for at least half an hour after cessation of pulse. Complete insensibility. Operation just commenced.	? Respiratory paralysis.	
70	45	M	To make incisions for extravasation of urine.	Inhaler 1½ drs. used	P	The addition of half a dram of chloroform produced insensibility and inhaler removed. Face became pallid. Pulse fluttered, and ceased. Respiration continued for one or two minutes. Anæsthesia. Operation completed.	? Syncope.	
71	28	M	Amputation of foot for an old injury	Inhaler 1 dr used	P	When about half a dram had been taken pulse suddenly failed. Face pallid. Inhaler removed. Gave a few gasps, passed urine and died. Not under influence. Operation not commenced.	Syncope.	Had been fully under influence for an hour and a half for a previous operation. Intemperate.
72	24	M	To apply nitric acid to syphilitic sores	Cone of lint covered with oiled silk. About 2½ drs. given at intervals.	P & R	Resisted the application of the acid. Struggling suddenly ceased. Face pallid. Pulse and breathing stopped. Artificial respiration produced a few inspiratory efforts. Imperfect anæsthesia. Application		
73	57	M	For delirium tremens, following a fracture of tibia and fibula involving the knee joint	Piece of lint. About ½ dr		tion commenced. Dead in twenty minutes. After two or three inspirations the man 'writhed' and fell back dead. Not under influence.	? Syncope.	Very intemperate.
74	50	F	To reduce dislocation of shoulder	"A simple compress."	R.	Reduction effected. Chloroform removed. Face became congested. Respiration failed then stopped. Death like pallor. No pulse. Artificial respiration and galvanism caused inspiratory efforts, but no return of pulse. Complete insensibility. Operation completed.	Respiratory failure and syncope.	
75		F	To relieve neuralgic pains	Upon a cloth.		The last dose given at nine o'clock. Found dead at ten. Supposed to be asphyxiated. Had taken it twice to insensibility on the same day.	? Asphyxia.	In the habit of taking chloroform, in this way, very frequently and in enormous doses. Very intemperate.
76	55	M	Perineal section for old stricture of urethra.	Inhaler. About 1 dr	P	Took chloroform quietly; breathing natural. Face turned pale, and pulse ceased. A few faint inspiratory efforts afterwards. None followed artificial respiration. Complete anæsthesia. Operation just commenced.		

DEATHS UNDER CHLOROFORM.

CASES FROM ROYAL MEDICAL CHIRURGICAL SOCIETY'S REPORT BETWEEN 1848 AND 1860 (continued).¹

1 Reference	2 Age.	3 Sex.	4 Operation and duration of administration.	5 Method of administration	6 P or R	7 Symptoms occurring under anæsthetic.	8 Assigned cause of death.	9 Remarks.
77	29	F	Extraction of tooth 4 minutes.	Handkerchief folded in a cone. About 1 dr	P	Forty drops sprinkled on the handkerchief produced excitement after 1½ minutes to 2 minutes inhalation Twenty more were added, and the excitement passed away I also good breathing calm; eye sensitive to touch Suddenly the head fell to one side, face became pallid, pupils dilated pulse ceased; she gasped a few times convulsively Artificial respiration and galvanism produced a few inspiratory efforts but no return of pulse. Partially under influence Operation not commenced. Death in less than four minutes.	? Syncope.	Highly nervous and hysterical. Sitting posture.
78	42	M	Excision of the elbow joint (following injury a month previously)	A piece of lint 2 drs, the second dram applied four minutes after the first.	P	At first breathing regular and pulse somewhat quickened, about one minute after the second dram was applied the man struggled and tried to raise himself; the pulse suddenly failed, breathing continued for some minutes, and the lips remained florid The tongue was immediately drawn forwards, artificial respiration and galvanism commenced, and continued for three quarters of an hour but of no avail Slightly under influence. Operation not commenced	? Syncope P M Heart and right lung healthy the left so infiltrated with tubercle as to render it almost useless for respiration.	
79	30	M	Operation for removal of necrosed portion of tibia. 6-7 minutes.	Inhaler About 2 drs	P	Took the chloroform well, breathing regular and even, as also was the pulse Operation commenced in 5 minutes, and a minute later the pulse, which was continuously watched ceased instantaneously the breathing continued unchanged for several seconds when the face became pale, and the respirations lower, and soon stopped Ammonia to nostrils, cold affusions, artificial respirations by compression of chest and by Sylvester's method, galvanism to cardiac region, and two needles passed into the heart produced no result. Complete anæsthesia Operation commenced Death in 6 to 7 minutes from commencing to inhale	? Syncope 1 M 23 hours after death Brain dark vessels congested especially those of the cerebellum 1 or 2 cardiacum contained a quantity of turbid yellow serum Heart mark of one needle about an inch above the apex the other an inch above this both in left ventricle which was partially contracted right not so valves healthy slight fatty deposit amongst fibres of right ventricle none on left side to the eye the muscular tissue of the heart was perfectly healthy lungs healthy slight congestion below and behind on both sides abdominal viscera normal but rather congested. The blood was universally fluid	Apparently a very healthy man.
80	28	M	Operation for fistula in ano 8-10 minutes.	Inhaler 1½ drs.	P	He breathed quietly for 6 or 8 minutes, and then struggled violently Had a sort of tonic spasm back curved so as to rest on his head and heels. The chloroform was suspended during this excitement. Pulse regular, good The inhaler was about to be re-applied, when the pulse in the temporal artery intermitted twice, and ceased. The body became ashy pale, patient gave 3 inspirations each shorter than preceding and breathing stopped, pupils natural. Cold affusion ammonia to nostrils Artificial respiration by Sylvester's method, and galvanism, were of no service No heart sounds could be heard. Partially under influence Operation not commenced. Death in 8 to 10 minutes.	? Syncope P M 48 hours after death Heart apparently healthy so far as muscular tissues are concerned rudely in colour; cavities dilated, and their walls thin Lungs universally adherent they contained some scattered tubercle and one small vomica. Liver large, pale fatty Kidneys natural	Not good health. Intemperate On Jan. 10, 1863 he had been operated on, under chloroform, for an exostosis of the femur, without any ill effects from its use.

DEATHS UNDER CHLOROFORM

CASES FROM ROYAL MEDICAL CHIRURGICAL SOCIETY'S REPORT BETWEEN 1848 AND 1860 (*continued*)

1	2	3	4	5	6	7	8	9
Reference.	Age.	Sex.	Operation and duration of administration.	Method of administration.	P or R.	Symptoms occurring under anæsthetic.	Assigned cause of death.	Remarks.
41	27	M	Operation for phimosis.	Weiss apparatus.	P	Was a little nervous, pulse good. In about 4 minutes face became slightly congested, and pt struggled to rise in bed. Face became dusky and lips blue. Cold affusion to face and compression of ribs caused a deep inspiration but pulse could not be felt. Artificial respiration and other measures were tried. He breathed at intervals several times but respirations became fainter, and at length ceased. Partially under influence. Prepuce removed.	? Syncope	He expressed no dread of chloroform but always had a great horror of it, and possessed an idea it would kill him.
42	14	M	Extraction of tooth.			The patient was seated. He had syncope, and died.	Syncope	Sitting posture.
43	60	M	Reduction of dislocated hip 20 minutes.	Apparently on handkerchief.		Very violent efforts necessary for reduction, which was at length accomplished, when symptoms of "cerebral congestion" set in. "Never fairly under influence." Operation completed. Death in 20 minutes after the chloroform was removed.		
44		M	To reduce a dislocated humerus.		P	Took chloroform readily. Just as reduction was effected pulse stopped and after a few gasps, breathing also. Artificial respiration and galvanism produced no effect. Under influence of chloroform operation completed.	? Syncope.	
45	22	M	Amputation of leg at the lower third for disease of the bones of the foot.	Piece of lint "A considerable quantity"	P	The man moved the limb slightly and more chloroform was applied when he suddenly became deathly pale and his pulse ceased. "Aspect like that of a corpse. The tongue drawn forward, and artificial respiration by compressing the chest kept up for half an hour. Efforts at intubation occurred at intervals of from thirty seconds to a minute for eight or ten minutes after the pulse had ceased—some of them of considerable force—so as to lead to a hope of a favourable issue but no return of pulse or of colour to the face. Once or twice with intubation, a movement of the neck and right arm. Galvanism produced no effect beyond a quivering of the muscles. Anæsthesia produced without anything unusual occurring. The limb was removed and the arteries were being tied.	? Syncope. P M twenty hours after death. Blood perfectly fluid like thin tar and water. Heart flabby moderately full no coagulum valves healthy muscular substance healthy both to the eye and under the microscope. Lungs contained more air than usual everywhere crepitant, did not collapse much on opening chest, no tubercle anywhere. Liver and kidneys normal.	Patient very wasted and debilitated from disease supposed to be phthisical.

CASES BETWEEN 1860 AND 1891 FROM PUBLISHED RECORDS

1	27	M	Avalulsion of great toe-nail. 2 or 3 minutes.	On towel.	P	The first two doses (? amount dropped on towel) produced no effect the third produced insensibility. The operation took but a minute or two and was completed but patient never returned to conscious state. Colour of face changed and pulse failed. Artificial respiration for $\frac{1}{2}$ an hour was useless.	Syncope. "The chloroform given in a dangerous way (open towel) instead of an inhaler."	Was suffering from cardiac disease as shown by P M. Had taken chloroform repeatedly on previous occasions.
2	?	M	Avalulsion of toe-nail.		?	?	?	?
3	?	M	To quiet fit of mania.	On lint.	?	?	? Syncope. Congestion of lungs.	Lunatic subject to violent fits of mania. In the last stage of exhaustion. Had often taken CHCl ₃ before.
4	40	M	For circumcision.	Napkin $\frac{1}{2}$ ozs.	R.	Stertorous breathing followed by failure of R. Measures resorted to were artificial R., galvanic battery to chest and neck. Inflation of lungs by tube and bellows rubbing limbs.	? Syncope. P M. Heart fatty. Lungs congested with apoplectic clots. Oedematous and less crepitant than usual.	

DEATHS UNDER CHLOROFORM
CASES BETWEEN 1860 AND 1891 FROM PUBLISHED RECORDS (*continued*)

1 Reference.	2 Age	3 Sex	4 Operation and duration of administration.	5 Method of administration.	6 P or R.	7 Symptoms occurring under anæsthetic.	8 Assigned cause of death.	9 Remarks.
6	42	M	For removal of lipoma on back 3 or 4 minutes	On single fold of thin lint. $\frac{1}{2}$ dra.	P & R.	Patient became excited, struggled and talked. This ceased and face became congested and breathing stertorous. On patient being turned over on left side breathing ceased suddenly. Artificial R by Marshall Hall's method and electro magnetism employed for 1 hour, but failed. No P or heart beat observed after R first ceased.	Failure of R. and heart action together. P M Lungs engorged with venous blood, heart large flabby, myocardium soft ventricles thinner than usual right side distended, left empty, blood fluid.	Patient a tall, stout, muscular man, inveterate drinker. Anæsthetic given at his own request, though dissuaded by surgeon. Chloroform quite pure.
7						When untoward symptoms came on artificial R resorted to contraction of heart kept up for $1\frac{1}{2}$ hours, and a few natural respirations obtained.		
8	24	M	For ingrowing nail.		P	After cessation of pulsations of heart patient made at intervals spontaneous inspirations and expirations.	? Syncope.	
9	40	M	For amputation of leg. Administration just begun.	Diluted.	P & R	Had scarcely made 4 inspirations when R and circulation were suddenly arrested, and so remained in spite of all means employed. [Surgeons objecting to chloroform being given and man wishing for it a small quantity at some distance from mouth was given.]	? Syncope.	Strong man. Leg crushed by fall from horse. Syncope at time of accident. Very nervous.
10		M	For operation for glaucoma. $\frac{1}{2}$ hour		R.	Sickness, the "anterior chamber of eye just opened filling with blood sudden fit, gasping &c. A crowd assembled round patient. Marshall Hall's method of artificial R. tried rubbed with ice for $\frac{1}{2}$ hour, P keeping good. At length I ceased.	?	Patient a strong and muscular man; the operation very trivial.
11	7	M	For tracheotomy for laryngitis			Patient seemed relieved by inhaling the CHCl_3 but no sooner was the tube within the trachea than he gasped and died. Artificial respiration was resorted to for 25 minutes cold water affusions and external stimulants. All with no effect.	? Asphyxia. P M Tissues of larynx infiltrated, general engorgement with marks of ulceration lymph puriform; epiglottis thickened and erect	Symptoms of laryngitis very urgent pulse 120, vital powers oppressed.
12	31	M	To induce sleep in delirium tremens.	Handkerchief.	R.	R impeded Chloroform suspended. Artificial R latent gave one deep breath and two slight ones. Other means resorted to were pulling out tongue, cold affusions rolling body on side, continued for 20 minutes with no avail.	? No P.M. allowed	Intemperate for long time.
13		M	Extraction of tooth	On handkerchief.	?	After extraction of tooth convulsive agitation set in which became violent, and patient expired. Restorative means used but not stated.		Sitting posture.
14			Extraction of tooth.					Sitting posture
15					R	Sudden embarrassment of R. and sudden dilatation of pupils	Suffocation. P M Lungs studded with tubercles and gorged with blood.	
16	32	M	Amputation of left leg for scrofulous disease.	Fold of bandage	P	Patient seemed to come rapidly under influence when suddenly sphincters relaxed, lips quivered and patient died. Breathing continued after heart ceased beating. Galvanism and artificial R. used to restore life.	"Fear, Debility, and Chloroform (Verdict of jury) P M Right cavities of heart filled with fluid blood.	Debilitated.
17	35	M	Passing catheter	3U (on lint)	R.	Operation about to be begun when patient ceased to breathe and animation seemed suspended. Galvanism and artificial inflation in turn employed but failed. Pupils dilated, lips livid.	Failure of R P M Pyelonephritis left kidney. Right kidney healthy, slightly enlarged, walls of bladder thickened urethra obstructed.	
18								

DEATHS UNDER CHLOROFORM
CASES BETWEEN 1860 AND 1891 FROM PUBLISHED RECORDS (*continued*)

1	2	3	4	5	6	7	8	9
Reference.	Age.	Sex.	Operation and duration of administration.	Method of administration.	P or R.	Symptoms occurring under anæsthetic.	Assigned cause of death.	Remarks.
9	50	M	For removal of internal piles.	Hollow sponge. 3½j nearly	P	While struggling continued some stertor appeared. In another minute full stertor face dusky and livid, without pallor. P ceased and R. became slower operation not begun. Measures adopted were Artificial R. slapping face and chest with wet towel blood letting from jugular vein rubbing limbs electro-magnetism.	Syncope. P.M. Heart loaded with fat, muscular substances thin and weak, walls of right auricle and ventricle in state of fatty degeneration, same cavities gorged with fluid blood.	Patient large, stout, very muscular abdomen prominent. Seemed given to drink. Arcus senilis P and R. natural.
20	8	M	For plastic operation for deformity caused by burn on chin.			Just before conclusion of operation patient fainted. Measures employed were artificial R. then warm bath and galvanism. Was recovering from CHCl ₃ , when bad symptoms came on.	Paralysis of heart. P.M. appearances nil	
21		M	For reduction of fractured ankle					
22	36	M	For putting stiffened leg in splint in case of diseased hip-joint.	3jss. Snow's inhaler	P	After inhaling for 1 minute had violent shaking fit. Inhaler was removed, and he became calm. CHCl ₃ again given when at rigid stage and was trying to raise himself muscles relaxed rapidly he fell back became pale breathing laboured and I hitherto good stopped. Measures adopted were artificial R. (for 1½ hours) galvanism acupuncture	? Syncope P.M. Heart large, cavities full of fluid blood loaded with deposit of fat Liver kidneys and brain much congested.	
23		M	For removal of two cysts—one on lid, other on tongue	3j On lint.	P	On inhaling patient became excited when convulsions ceased fell into collapse had 3 violent fits of sneezing and heart ceased beat breathed several times at long intervals	Syncope.	Patient a feeble subject.
24	5	M	For removal of left testis for malignant disease. 4 minutes.		P	Soporose breathing commenced, pulse became feeble chloroform withdrawn but P rapidly failed and in 20 seconds ceased beating. Patient made 8 or 10 regular and 2 or 3 irregular respirations and inspirations after heart ceased. Cold water fresh air Marshall Hall's method of artificial I ammonia to nostrils friction to extremities and galvanic current from spine through thorax to diaphragm. All these for 1 hour	? Syncope P.M. No trace of organic disease; blood fluid and organs generally congested. When heart ceased beating ventricles dilated valves quite healthy no fatty degeneration	Patient a fine muscular man.
25	32	M	For fistula in ano 10 minutes.	On lint folded on handkerchief. ½ oz. Not given in measured quantity	R.	Patient struggled violently raised him self on seat and stopped breathing. Window was opened. Marshall Hall's method of artificial R. and other methods tried.	Paralysis of R P.M. Heart and lungs found to be extensively diseased. This verdict was disputed as P.M. took place 16 days after death	Patient in excellent state of health, quite fasting before administration heart and lungs in excellent state.
26		F	For examination of shoulder joint.	Quantity small				Chloroform used of unexceptionable quality
27	16	M	Amputation of great toe for disease of bone. 5 minutes.	No apparatus to determine quantity	"			Patient said to be very healthy
28	40	F	For removal of tumour on lower jaw	2 dr (Is not quantity under stated?)	P	Before operation was finished patient became slightly conscious. After second dose she took one inspiration and pulse stopped suddenly. She gave three or four gasps, and in half a minute was dead. Every effort made to restore animation without effect.	P.M. Fatty degeneration of heart.	
29	17	F	For operation on sphacelated wound consequent on a fall.	2 dr Napkin.	P	Operation begun, after second dose took one inspiration and P ceased suddenly. Every effort made to restore animation with no avail	? Syncope. P.M. Heart feeble and fatty	Patient of nervous temperament and suffering from fatty degeneration of heart. Chloroform given very cautiously
30	21	M	For amputation for diseased knee	Snow's inhaler	R.	R. failed. P kept good. Larynx opened stimulant given Marshall Hall's method of artificial P kept up	Failure of R. P.M. appearances nil	
1	2	M	Fracture of leg					

DEATHS UNDER CHLOROFORM
CASES BETWEEN 1860 AND 1891 FROM PUBLISHED RECORDS (*continued*).

1 Reference.	2 Age.	3 Sex.	4 Operation and duration of administration.	5 Method of administration.	6 P or R.	7 Symptoms occurring under anæsthetic.	8 Assigned cause of death.	9 Remarks.
32	29	F	For removal of small tumour of gum (? epulis).			Died in an instant.	P Syncope.	
33	60	F	For reduction of strangulated umbilical hernia. 11 minutes	3i, 160 minims	P & R	Operation commenced and twice interrupted (1) by coughing and (2) by vomiting. At 4 minutes after the inhalation the operation about $\frac{1}{2}$ completed, was stopped, and patient became so feeble that restorative measures were used. In 4 minutes more, died.	Protrusion of stomach, together with previous great exhaustion. P and R failed till both ceased. Stomach completely strangulated and ruptured in the peritoneal coat and back of the cardiac pouch.	Patient corpulent, greatly exhausted, had vomited for 6 days, and had been constipated 3 days. Was operated on for strangulation 10 years before.
34		M	For amputation of finger		P	Died instantly. P ceasing and face becoming discoloured. Artificial R. and galvanism tried without success.	Syncope. P M Lungs un-healthy, heart fatty.	
35		M	For fistula in ano.		R	Convulsed. Allowed little fresh air, CHCl ₃ again given still convulsed, suddenly ceased breathing, usual remedies for resuscitation.	Apnoea (probably) but would seem from symptoms to have been syncope.	
36		F		1 dr Handkerchief.	R.	Head was observed to fall on one side and the breathing ceased suddenly.	Syncope.	A nervous hysterical woman.
37								
38								
39	38	F	Vesico-vaginal fistula.	Inhaler 3iiss-iiij	P	Suddenly seized with spasm of respiratory and other muscles. P failing though heart beating. Artificial R., galvanism and cold affusions used in vain.	Syncope P.M. Heart flabby and fatty	Weak, irritable and nervous, had had 9 children and 1 miscarriage at end of 3rd month. From end of last confinement had suffered from incontinence of urine.
40		F	For removal of tumour at back of neck.			Operation skillfully performed but insensibility protracted. At end of $\frac{1}{2}$ hour limbs moved spasmodically, ending in convulsion and death.	P Syncope.	
41	41	M	For excision of joint (right arm).		P	Pulse became feeble galvanism and other remedies applied for $\frac{1}{2}$ hour with negative result.	P M Heart fatty and weak in structure.	
42		M						
43		F	For fistula 7 minutes.	2 dr	R. & P	Patient struggled slightly. After operation consciousness did not return and R became slower and ceased in 3 minutes. Measures adopted were cold water in face, sal volatile, galvanic apparatus and Marshall Hall's method to procure artificial R.	Cessation of R. apparently, but medical opinion inclined to rank it under heart failure. P.M. Heart fatty flabby, and deformed, walls of left ventricle very thick, of right very thin. Liver enlarged pressing upwards against lungs. Lungs very small, gorged with blood and with black patches, showing death from chloroform.	Patient large and well made, seemed to have no heart disease, but suffered occasionally from indigestion.
44	16	F	For operation on bare lip 5 minutes (about)	(1) By inhaler, with no effect. (2) on lint. Patient seated in chair	P	Before complete insensibility, pupils dilated rapidly patient fell back, became pale and lips bluish. Artificial R. tried for $\frac{1}{2}$ hour with no effect.	Syncope. The pulse was not felt continuously but occasionally. The coroner's opinion at inquest was that continuous watching of P might have saved life of patient. The operator Mr Gay, considered immediate cause of death to be palsy of involuntary muscles (see letter, <i>Ibid</i> p. 578)	Heart considered sound. Sitting posture.

DEATHS UNDER CHLOROFORM
CASES BETWEEN 1860 AND 1891 FROM PUBLISHED RECORDS (*continued*)

1	2	3	4	5	6	7	8	9
			Operation and duration of administration.	Method of administration.	P or R.	Symptoms occurring under anæsthetic.	Assigned cause of death.	Remarks.
11			For passage of catheter.	4 drs.		"The reporter thought the man had fainted. It was not the usual congestion." Died in an instant, 20 ozs of blood were taken from arm as chloroform restorative.	Syncope.	Perfectly healthy.
12	F		Extraction of teeth.			After 6 or 8 teeth had been extracted patient ceased struggling—whole system became relaxed and appearance death like. Efforts for resuscitation made for 5 hours which proved unavailing.	Syncope. Inque and P M held but result not known.	Sitting up.
13	M		For removal of tumour affecting nasal region. 3 minutes.	Towel.	R.	Profuse hæmorrhage. R. became very low. Artificial R. resorted to (Sylvester's method) succeeding for a while but in 23 minutes respiration ceased entirely.	"Apnoea from effects of CHCl_3 and loss of blood." P.M. Heart and lungs healthy. Lungs congested with blood in patches. fluid blood on both sides of heart. Liver and kidneys gave signs of death from suffocation. "Died from the effects of the vapour."	
22	F		For removal of tumour of urethra.					A question arose as to the quantity administered to patient on a similar occasion two years before, and the absence of books of reference in such cases in the hospital. The jury expressed an opinion that proper case books for reference should be kept in the hospital.
14	M		Avulsion of great toe-nail.				Fatty degeneration of heart.	
15	F		For extraction of tooth.	Napkin.	P & R.	Only slightly under after operation face became livid jaws clenched breathing arrested patient died.	Syncope.	Sitting posture. When examined before-hand no trace of heart disease.
16	M		Amputation of leg.	Napkin.	P	Patient never fully anæsthetized during operation screamed out then signs of falling circulation came on, and death ensued in 10 minutes. Methods resorted to were cold affusions ammonia, drawing forward tongue, artificial R. and galvanism.	Shock. Doubtful whether CHCl_3 exerted any influence. P.M. Heart healthy. Lungs congested. Brain very large and well developed (60-80 oz. avd.). Syncope.	No blood in state of heart appeared to forbid use of chloroform.
17	M		Removal of bone from right foot. 2 to 3 minutes.	Snow's inhaler. 40 minutes.	P	P suddenly became imperceptible. Pupils not dilated and breathing natural. Inhaler removed. R. became deep and sobbing and tongue protruded between teeth. No return of P., but R. continued 1 minute after P. ceased. Restorative measures were—Cold douche, brandy injection per rectum, solution of ammonia on lint to nostrils galvanism (forceps not needed as tongue did not fall back), artificial R. for half hour.	Syncope. P.M. Lungs healthy. Right more congested than left. Ventricles contracted and empty auricles with blood valves and muscular tissue healthy. Br microscopical examination ultimate fibres free from oil globules and striæ well marked. Walls of left ventricle slightly hypertrophied with dilatation Aorta healthy.	Patient healthy looking. By examination nothing to contraindicate use of CHCl_3 .
23	M		For cauterization of sloughing sore on penis.	Inhaler 2 drs in separate doses of 1 dr each.	P	After inhalation of first dose holding his breath and trying to avoid the vapour (which was diluted however) so that much was wasted. After he had spat second dose given but he struggled so much that P. could not be watched continuously. Sudden pupils became widely dilated and P. ceased. On removal of inhaler he drew deep gasping breaths for $\frac{1}{2}$ minute. Restorative measures cold splashings Marshall Hall's method of artificial R., and after by Sylvester's method, brandy injection, galvanism, friction.	Syncope. P.M. Heart of normal size, ventricles partially dilated and both with fluid blood. No valvular disease. No fatty degeneration.	Patient healthy looking. Chloroform given by his own desire.

DEATHS UNDER CHLOROFORM
CASES BETWEEN 1860 AND 1891 FROM PUBLISHED RECORDS (*continued*)

1 Reference	2 Age	3 Sex	4 Operation and duration of administration.	5 Method of administration	6 P or R.	7 Symptoms occurring under anæsthetic.	8 Assigned cause of death.	9 Remarks.
54		M	For amputation of leg for gun shot wound. 15 minutes	Sponge. $\frac{1}{2}$ oz.		Died 5 minutes after untoward symptoms set in.	P.M. Lungs and heart quite healthy	Had taken CHCl_3 in larger quantity before.
55	13	M					Syncope.	
56	2		For removal of finger 5 minutes.	On lint. 30 drops.				
57			For reduction of luxation of head of humerus.		P	After the reduction was completed it was perceived that the P at the wrist was gone. All the usual means resorted to in vain.	Syncopa. No P.M. permitted.	
58		M	Cataract.			Operation had just been completed when patient was observed to change colour, and in spite of the use of galvanism and other nervous stimuli he expired.	Syncopa. P.M. The heart was found in a very soft and fatty condition. No morbid sound had been heard previously by auscultation.	Had twice before been under CHCl_3 without bad effect.
59		F	For extraction of tooth.	Upon naphin 50 minims in two doses.	P	After extraction of tooth there was poenlarity in R which almost at once ceased and on feeling at wrist there was no P. Artificial R without effect.	Probably syncope characterised by spasm of left side of heart. P.M. Nothing abnormal. Left ventricle of heart firmly contracted, and cavities on left side empty on right side auricle and ventricle moderately distended, and there was no clot.	Sitting up. The patient had taken a larger dose of chloroform on a previous occasion with no ill effect.
60		M	For avulsion of nail	Handkerchief	P			Patient an apparently healthy man.
61	41	M	To facilitate catheterising 2 or 3 minutes.		P & P	I lips became blue, jugulars distended P and R ceased. 1 finger passed down epiglottis, deep inspiration vein of neck opened and 1 oz. blood let, then another inspiration. Tracheotomy artificial R, stimulation of diaphragm by induction apparatus, cold affusion, electricity to region of heart and acupuncture of heart. These measures revived action of heart for short while but it soon ceased.	Syncopa. No P.M. account furnished.	Was suffering from oedema and albuminuria following renal lina.
62								
63	11	M	Lithotomy		P & R.	P and R. ceased at same moment.		
64		M	For reduction of dislocated thumb. 3 or 4 minutes.	1 dr	P	P suddenly ceased beating, and in a moment patient was dead.		Patient strong and healthy. Was said to have been compelled to take CHCl_3 against his will.
65	15	M	For removal of necrosed bone from stump of amputated thigh.	2 to 3 dr	P		P.M. Right side of heart loaded with dark-coloured blood, and lungs highly congested.	
66	20	F	For extraction of teeth.	Sponge. 1 dr (in three portions).		After inhaling first two portions, three teeth extracted. Consciousness not lost. Remainder then given. Remaining teeth extracted. Sudden pallor R ceased, then P. Congestion of capillaries about neck and upper portion of chest pupils dilated. Measures adopted were External stimulation artificial R. and galvanism for $\frac{1}{2}$ hour with no effect.	Syncopa.	Sitting posture. Had taken CHCl_3 for extraction of 6 teeth 2 days previously.
67		M						
68		F	For strabismus.	1 $\frac{1}{2}$ drs.	P R.	Insensible and pulseless breathed heavily at intervals. Pupils dilated and R. ceased. Artificial R. resorted to, but death took place in two hours.	Syncopa. Cessation of R.	
69	8	M	For strabismus.			Died before commencement of operation.		
70		M	For operation about thigh.		P		Inhalation of chloroform	

DEATHS UNDER CHLOROFORM

CASES BETWEEN 1867 AND 1891 FROM PUBLISHED RECORDS (continued)

1	2	3	4	5	6	7	8	9
Case	Operation and duration of anaesthesia	Method of administration	P or R	Symptoms occurring under anaesthesia	Assigned cause of death	Remarks		
111 M	For removal of ligature after removal of diseased testicle. 5 to 7 minutes.	Towel cone. 1 dr.	P & R.	After having passed into second stage suddenly became stereotyped, underwent spasm (opisthotonic) for about 1 minute, and ceased to breathe. Efforts to restore action of heart and lungs failed. Means employed were. Cold effusion drawing out tongue, artificial R., ammonia to nostrils and heart, galvanism.	Syncope. Paralysis of heart. P.M. Kidney congested measured 7 inches in length by 4 in width, resembling larger red kidney described by Bright. Slight accumulation of fat over posterior diaphragm and on surface of heart. Brain effusion between dura and pia mater and between latter and arachnoid. Cessation of heart's action may have been caused (1) by convulsion causing effusion on brain—convulsion due to blood charged with excrementitious matter (2) overloaded blood charged with CHCl ₃ acting on heart.	Had twice before taken CHCl ₃ for removal of testicles large doses, 20z and 14oz. On second occasion was suffering from "Dengue."		
112 F	Examination of uterus to elicit	2 dr.	R.	Before examination could be made patient ceased to breathe and died.	P.M. Heart liver and kidneys somewhat fatty. Lungs "hypostatic congestion."	Patient was stout. Chloroform was carefully administered.		
113 M	For operation on external and inguinal hernia. 25 minutes (about).	SNK. Lankerscheil. 1½ ozs.	R.	Vomited fluid entered into wind pipe (aspiration) choked, and turned black in face. Position of patient changed ammonia and other restoratives given but death took place in very short time ("less than 2 minutes" according to one account).	Asphyxia.			
114 M	For operation on knee joint.		P.	After completion of operation, P. suddenly ceased to beat. Artificial R. for an hour and other means employed without effect.	Syncope.			
115 M	Lithotomy.	Napkin folded conically. More than 1 dr.		Operation just begun for which little more CHCl ₃ given. Patient made one or two R.s when condition became critical. Measures adopted were. Cold effusions spanking striking chest, pressing a dome, leverage over for artificial R. All with no avail.				
116 M	For disarticulation of elbow on pyrexia.	Towel.	P & R.	Lividities cessation of P and R. Measures adopted were. Drawing forward tongue artificial R. (Marshall Hall's method) for 1½ hours, ammonia to nostrils galvanism through thorax and other parts.	"Syncope" P.M. Heart 1½ oz., walls bloodless tissue easily torn, fatty degeneration lungs in itself congested liver fatty kidneys congested brain effusion of blood on dura mater little serum in lateral ventricle. Asphyxia.	On last admission presented usual appearance of having been on debauch.		
117 F	For removal of wart about vulva. ½ minute.	In compress (quantity small).	R.	Exhibited symptoms of asphyxia. Restorative efforts used unremittingly without success.		Patient had taken CHCl ₃ successfully three weeks before for same operation.		
118 M	Removal of cystic tumour of neck.		P.	Patient seized with violent exclamation while large vein at bottom of ear poured forth much blood. Deligation of vein difficult because of convulsions but vessel having been secured and wound being dressed, and chloroform removed some minutes P. at wrist opened and patient died after artificial R. for 1½ hour.	Syncope. M. Broca thought the air in veins caused death, but this no confirmed by P.M.	Patient found to have been subject to epilepsy.

Lecture

ON

CERTAIN BRANCHES OF OPERATIVE SURGERY

BEING THE SECOND HUNTERIAN LECTURE FOR THE SESSION 1892-93

Delivered before the Hunterian Society on Feb 22nd, 1893

By WALTER RIVINGTON, B.A., M.B.,
M.S. LOND., F.R.C.S. ENG.,
CONSULTING SURGEON TO THE LONDON HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—When I was invited by the President of this Society, in the name of the Council, to deliver the second of the recently established Hunterian Lectures for the current session, I felt that my long connexion with this Society in various capacities rendered it obligatory on me not to decline the invitation. Moreover, the opportunity was thus afforded to me to utilise a small portion of my stock of still unpublished material, and I have, therefore, selected as my subject certain branches of operative surgery which admit of illustration from my own experience and from cases which have been under my care. When I look back to the time when I held the office of house surgeon to the London Hospital, a period of more than thirty years, and compare the state of operative surgery in that institution and at that time with its state now, the progress which has been made seems little less than marvellous. The surgical staff, consisting of three surgeons and three assistant surgeons, operated on one regular operating day (Wednesday afternoon) and held consultations on important cases on the same day. The operative surgery of the hospital then consisted mainly of amputations, the relief of strangulated hernia, if possible, without opening the sac, on which great stress was laid, the ablation of external tumours, the occasional ligation of an artery or nevus, tenotomy, colotomy in the lumbar region, lithotomy and the removal of carious and necrosed bone. Mr. Luke was the great advocate of Petit's operation in hernia, and his papers in the Royal Medical and Chirurgical Society's Transactions show that he met with great success, all the more, perhaps, because he did not spend much time over taxis. When he had to open the sac he would do so by a small incision over the neck to relieve the stricture at that part, and then, if possible, reduce the gut without further exposure. So far as his operations went, Mr. James Luke was one of the most skilful and neatest of operators and it was said of him by Mr. Nathaniel Ward, a surgeon of great capability himself, that "Mr. Luke would have operated well with a fire shovel." Lithotomy was not in favour, but a former President of this Society, Mr. Thomas Bilzard Curling, who was a sound, scientific and enterprising surgeon in his day generally on the watch for new but safe procedures, adopted it now and then. It will be remembered by former students of the hospital that in the performance of lateral lithotomy Mr. Curling always used the old fashioned gorget, a selection which prevented his operations from competing in elegance with those of his colleagues, Mr. John Adams, a very skilful lithotomist, and Mr. Critchett, who was distinguished for coolness and neatness in all that he undertook. Mr. Critchett was rather partial to Allarton's operation for stone in children when practicable and always kept pace with the advances in operative surgery. On more than one occasion he ligatured the main trunk of an artery for hæmorrhage from a distant but not readily accessible branch. One of his cases was a ligation of the superficial femoral for hæmorrhage from a compound fracture of the tibia and fibula. When he resigned his appointment as surgeon to the hospital to devote himself exclusively to diseases of the eye, general surgery lost a very able exponent.

Excision of joints was quite in its infancy and it was an event when in a theatre crowded with students Mr. Curling performed excision of the elbow joint in January, 1858.¹ Soon

afterwards Mr. Critchett excised the knee in the case of a boy. About the same period Mr. Curling undertook ovariectomy, I believe for the first time, at the London Hospital. Spencer Wells had only just begun to operate, and ovariectomy, whose mainstay in the metropolis had been Baker Brown, had scarcely emerged from its probationary and apologetic stage, for the mortality was high. "Between 1852 and 1856" says Mr. Greig Smith, "Baker Brown operated nine times, with seven deaths, and this mortality checked him for four years, when he began a career which, but for its untimely and unfortunate termination, would probably have done much for ovariotomy."² In point of fact, abdominal surgery in all its branches, cranial surgery, spinal surgery and thoracic surgery have been almost entirely created or revived during the last thirty years, and so great has been the extension of operative measures that the five surgeons and four assistant surgeons now comprising the surgical staff of the London Hospital have each their own day and hour for operating. As consulting surgeon to this institution I have never received any notice of consultations, for there do not appear to be any, but I receive regularly notices of operations and occasionally lists of the operations of a single surgeon with between ten and twenty items for an afternoon, many being procedures of the first magnitude, including two or three abdominal sections, radical cures of hernia, ligation of large vessels and perhaps the removal of a "fore-quarter"—an operation recently imported from France, and which one would rather have expressed otherwise. In addition to the increase in cases suitable for operation, the surgical staff of the hospital enjoy one great advantage over their predecessors. Three years ago it was discovered that the drainage of the hospital and the sanitary condition generally were most seriously defective, and £7000 had to be expended in remedying the defects. There can be no doubt that these defects have been responsible in past years for the loss of cases after operations which would otherwise have recovered and for the prevalence of septicæmia and pyæmia at the London Hospital.

The rapid growth of operative surgery in our time has been due, as we all know, in the first place to the introduction of anæsthesia, by which the dread of the knife has been largely removed and the comfort and convenience both of the patient and the operator have been secured, and, in the second place, to the general acceptance of principles of antiseptic and aseptic surgery or, in other words, surgical cleanliness and drainage, by which the rapid healing of wounds is favoured and the supervention of local and constitutional complications, infective inflammations, erysipelas, septicæmia and pyæmia prevented. The discovery of the part played by micro-organisms in the processes of disease, the improvement in surgical instruments and appliances the more speedy and certain methods of arresting hæmorrhage, the perfecting of the details, or technique, as it is called of individual operations, the more efficient methods of diagnosis, more especially through the illumination of cavities previously hidden from view have all contributed to stimulate the invention and inflame the ardour of surgeons, and we are constantly hearing of new procedures for the cure of deformities, the removal of diseased organs and tissues, and for repairing the effects of accident. Hence it is that one of the chief snares which the surgeon of the present day has to avoid is the danger of being too

owing to the circumstance that a student who was present wrote a poem on the event called *The Lay of the Resection* under the nom de plume of Innocent Bohn. As the lines faithfully rendered Mr. Curling's observations I hope I may be pardoned for quoting them—

This silence for great Thomas has turned him round to speak—
This operation as you know was planned for Thursday week.
Mass Thomme propose—twice cup and lip there 'very old a slip alas!
So it was here the patient's arm was seized with erysipelas
Small matter since the thing is done the annoyance of delay
But of the operation I've a word or two to say
Report has been resection here is put upon the shelf
It's scarcely true—some years ago I did the thing myself
Nor would my colleagues ever refuse to operate forsooth!
He glances at Jacobus well! I hope he tells the truth.
Besides we're pupils of John Scott, and tis our higher praise
To save a joint, than cut it out, and bear away the bays!
And then it makes a difference whichever is the joint meant,
Whether tis proper to excise or smear it o'er with ointment
Excision of the elbow is objected to by few I see
Excision of the knee must still be held to be *sub judice*
The greatest difficulty is to make a fit selection
That done not one of us denies approval to resection."

Mr. James Luke

† The bays had reference not only to the laurel crown of the victor but to a piece of red cloth which was always placed under the part to be operated on. This objectionable and germ holding baize has now given place to mackintosh.

² Abdominal Surgery, p. 125.

¹ At the conclusion of the operation Mr. Curling made some remarks on excisions which embodied the principles of conservative surgery. The substance of these remarks has been impressed on my memory.
No 3631

active, of doing too much rather than too little, whilst a do-nothing and temporising policy was the special temptation of former times. Mr Curling informed me that when he was assistant surgeon to the London Hospital he used constantly to supply his senior colleague with cases for operation and frequently suffered from the mortification of seeing such cases discharged from the wards without relief. Case after case even of necrosed bone—readily removable—met with this fate. The difficulty now is to restrain the surgeon from operating in unsuitable cases. When any new procedure is introduced it at once becomes necessary for every young surgeon to perform it as soon as possible if he is not to lag behind in the race for surgical honours. What a rush there was to do Ogston's operation for knock knee when it was first introduced. Every surgeon was envious of Ogston and was sorry that he had not thought of the procedure himself. Yet after a brief but not inglorious career, for there was much merit in the expedient, it was laid aside for the safer method of McEwen, and some, perhaps, who were loudest in its praise may have regretted that they ever performed it.

Another cause of the multiplication of surgical operations has been the increase in the number of surgical specialties. There is scarcely any organ in the body which is now left in the hands of the former tyrants of the medical world—the fellows of the Royal College of Physicians of London—for almost every organ and every system of tissue in the human frame is cultivated by a surgical specialist. The office of every specialist must be magnified—his domain must be extended to its utmost limits. "Diseases of the throat," for instance, receive a generous interpretation from the laryngologist and from the suffering public and include all sorts and conditions of maladies affecting the miscellaneous structures between the base of the skull and the diaphragm. New diseases and new ramifications of old disease are discovered by the specialist and new instruments are invented for their removal. Some years ago Dr Clifford Allbutt favoured the profession with a graphic description of the treatment which the long suffering uterus, and especially the cervix uteri, had to endure, and a few weeks ago, in his Bradshaw Lecture, Mr Christopher Heath was endeavouring to reduce the diseases of the nose to their lowest denomination. In the treatment of clubfoot there appears to be a danger that the safe and efficient operation of subcutaneous tenotomy which has conferred lustre on the name of Stromeyer, will be set aside for radical operations of doubtful value. Even the ear has not escaped the prevalent infection. Operations are now performed for the entire removal of an unperforated membrana tympani with the malleus, the incus and even the stapes.

The operative treatment of cancer, which has been extending itself in recent years, sometimes to the advantage and sometimes to the detriment of the individual patient, has been marvellously supported by the theory that cancer is only a local disease, at least in the first instance, as well as by the discovery of a "precancerous stage of cancer." No one can deny that there is and must be such a stage. The coming cancer does undoubtedly sometimes cast its shadow before, as exemplified in those cases of cancer of the breast which are preceded by eczema of the nipple as described by Sir James Paget.³ The difficulty lies in recognising conditions which are really precancerous and in distinguishing them from like conditions which are absolutely innocent. In many cases this is practically impossible. Are we then to cut the Gordian knot and to doom to operation every removable part which exhibits a degeneration, a suspicious alteration or deviation from the normal which may have excited the fears of the patient? On such a principle every mole, wart or excrescence, every scar every imperfect or damaged organ—all of which are prone to become cancerous—ought to be removed without delay. Then there are the doubtful and puzzling cases in which it is extremely difficult to determine whether the disease is cancer or not, and certainly far more difficult to say whether it is likely to take on cancerous action at a future period. Two or three such cases, in which the breast was the seat of the affection, have come under my notice, and in these I have usually advised delay. More than thirteen years ago a case of this kind came under my

care at the London Hospital. The patient has been under my observation ever since, and she is still alive and accessible. The particulars of the case, which was one of chronic induration of the breast with retracted nipple, I will now relate.—The wife of a labourer, forty six years of age, was admitted into the London Hospital under my care on July 19th, 1879, and was discharged on the 22nd. She was a healthy-looking woman, had borne seven children, six of whom are still living, and she had had three miscarriages. She always suckled her children for eight to ten months. At the time of her admission she had been married twenty-two years, and she had lived in the same locality all her life. The monthly period was just ceasing, and for the last twelve months her catamenia had been very irregular. She had been sent in for malignant disease of the right breast and as an urgent case for operation. Her medical advisers had told her that she would not live very long if she would not undergo an operation, and she had seen an eminent provincial surgeon who recommended her to have her breast removed on the ground that she was the subject of cancer. On examination the nipple of the right breast was seen to be retracted. The breast itself felt nodular, apparently from induration of the lobules, but on laying the hand flat on the organ and pressing it towards the chest no real tumour could be detected. The patient stated that the right nipple had always been small and that she seldom suckled with it. It had begun to recede two years previously, it was quite drawn in and could not be protruded. Both breasts were of fair size, well developed and of the same dimensions, and both were a little flaccid. Hard lobules could be felt in the left breast, but they were more pronounced in the right. Both breasts were very tender at each monthly period, and occasionally there was a thin watery discharge from the right nipple. The affection began with a pricking pain in the chest. Even now at times she has some uneasiness or pain either at the menstrual period or for two or three weeks, when it again disappears. The nipple always discharges a little. When she was in the hospital the case stood thus: no definite tumour in the breast, retraction of the nipple with watery discharge and hardness of the lobules, no perceptible glands in the axilla, skin over the breast healthy looking and freely movable, gland also movable and similar in appearance to its fellow save for the recession of the nipple, no family history of cancer, no wasting of any kind. From these features I diagnosed the case as one of chronic induration of the breast with retracted nipple and did not advise an operation. The patient herself had been much averse to being "cut about," as she expressed it, and received her reprieve with much satisfaction. Had the breast been amputated for cancer no doubt the case would have been quoted as an instance of cure by operation. Some may possibly think that it is safer to remove an organ of this kind, but I share the objection which the patient herself entertained to an avoidable mutilation.

With regard to operations for genuine cancer, I always doubted whether, *taken as a whole*, they succeeded in ensuring to patients operated on any real lengthening of life. General statistics, as distinguished from the complete statistics of individual surgeons, are most untrustworthy firstly, because they are largely compounded of the more or less favourable cases which have a tendency to be reported whilst the cases which are fatal after operation or which the operation does not influence for good are allowed to pass without notice, and, secondly because they include cases of very different kinds, some in which the disease was not cancer at all and others in different conditions and at different ages which are not comparable. Before statistics can be allowed to influence our decisions they ought to be thoroughly sifted and analysed so as to group together series of cases of a precisely similar kind both as regards age and exact variety and condition of the disease. If we look at cancer of the breast, for instance, how great is the difference in the course and duration of individual cases. Age, condition of the patient, and situation of the disease all have a modifying influence in regard to the rapidity of its development and the early or late termination of the case, and it is the same with cancer affecting other parts of the body. Undoubtedly there are cases of genuine scirrhus of the breast which have remained well after operation for a number of years—some few as they may be, for eleven or twelve some for seven or eight, some for three or four, but, on the other hand, there are many

³ Reference may be made to papers by Mr Batlin in vols. IX. and IX. of the Medical and Chirurgical Transactions and to Mr Bowley's paper in vol. LXIV. Mr Bowley gives thirteen cases. One is that of a lady aged sixty who had had the affection nearly five years. Mr Thomas Smith amputated the breast. Its structure was healthy except at the orifices of the ducts, and no growth was found in any part.

⁴ Mr Jacobson advocates removal of the breast in such cases. See a note to a very able and interesting article on "The Precancerous Stage of Cancer of the Tongue," Guy's Hospital Report, 1889, p. 215.

which speedily recur, some which recur in an acute form owing to the operation itself, and others which if let alone run a chronic course, with little or no pain, and even without ulceration. The chance that the surgeon will lengthen the life of any individual patient by an operation appears to me not to be a very hopeful one. Sometimes it is not greater than the chance in a lottery in which there are a few prizes and many blanks. Apart, however, from lengthening the short span of human existence there are, of course, considerations which may entirely justify the surgeon in recommending an operation for cancer. The removal of an otherwise irremovable tumour whose presence may be a source of anxiety, worry or actual suffering, the likelihood, or at least the chance, that if the disease recurs its recurrent condition may be more endurable than its primary state—as Sir James Paget believes though others think differently, the fact that sometimes, if not always, the general health of the patient, for a space at least, improves—are the surgeon's justification for recommending, and sometimes even for pressing, an operation on a patient. In some situations—for example, in the mouth—the removal of the disease, it may be with a considerable portion of the jaw, is a great relief, and if the disease recurs it may recur in the glands only, and the surgeon has rendered the last days of the patient comparatively comfortable.

All the considerations here advanced as favourable to operations for cancer I admit to the full, and as I have been in the habit of acting up to them in my own practice I can make a more forcible protest against the doctrine that all cases of cancer or suspected cancer wherein the disease can be removed are to be treated on the same lines and that operation is to be urged on everyone. We hear not very infrequently, of "cancers" which disappear or which turn out to be of an innocent nature, and others we meet with which would have lasted longer if let alone, for an operation may light up the activity of a previously quiescent or very slowly advancing disease and thus may shorten the existence which it was intended to prolong. Some operations, again, which are spoken of to the patient as being comparatively trivial and free from danger are very greatly the reverse. Excision of the mammary gland for cancer is generally represented to the patient as involving very little risk to life. Undoubtedly in the large majority of cases, especially when the operation is performed upon the ancient lines admitting of conjunction of flaps the wound will quickly heal often by the first intention, and the recovery will be rapid and for the time complete, but the modern doctrine that "cancer germs" are distributed widely in the apparently sound superjacent skin and in the axillary glands has led some to "return to the old plan of sweeping away everything and leaving a great hole at the primary seat of disease to fill up by granulations" as well as to supplement this with clearing out the axilla in a systematic manner. Whilst yet small, "the axillary glands and the whole fat and cellular tissue of the axilla can be pulled out with the fingers with the greatest ease." These are the words of Mr Mitchell Banks* who has been the most able, prominent and successful advocate of the new method, and he candidly admits that the operation performed in this thorough and sweeping way is "no longer a bit of surgical tailoring and that many more people will die from it," that "the opening of the axillary cavity adds not a little to the danger of the original operation," that "the wound is tremendous" that "the chasm left is something frightful to look at," and that "the whole procedure is accompanied with a very serious shock seeing that thirty to forty minutes is the very shortest time in which it can be satisfactorily done." In three of his cases, "when the highest point of the axilla was reached it was found that there were still glands so adherent to the vein that they could not be removed whilst the condition of the patients was such that it was clear that the sooner they were off the table the better, lest an immediate sinking should occur." The immediate mortality from this operation is calculated as amounting at present to 10 per cent., but Mr Banks reasonably believes that it is reducible to 5, 6 or 7 per cent. as he has boldly dealt with cases which other surgeons would have been averse from touching, in order to give the patient a chance. In other cases he thinks he was scarcely bold enough. That he would have been justified in declining to operate on the less favourable ones is shown by his statistics. Out of forty-six of his early series six died after the operation and eleven had speedy

recurrence of the disease, nine of the eleven being dead and buried before the lapse of twelve months, one living fifteen months and the last a little longer. In several of these eleven cases it was impossible to remove all affected glands. Mr Banks has done good service in pointing out that no one can tell the state of the axillary glands till he sees them and that until the axilla is opened no one can be sure what he is going to find. Over and over again he has taken out of the armpit glands seriously affected when no glands could be felt even by the most careful handling by several persons. Often, too, they have extended high into the axilla and even into the neck when they were scarcely palpable externally, and when exposed "some may shell out like peas and some may adhere to the vein like limpets to a rock." These statements I can myself confirm and they lend strong support to Mr Banks' contention that the axilla should always be explored in every case of removal of the breast for cancer, for, as Mr Banks observes, it is "worse than useless to make a great wound over the chest and leave affected glands in the axilla." With great ability Mr Banks contends that his method of making a clean sweep is the correct method of operating, and as the generality of surgeons do not adopt it in its entirety the following extract from Mr Banks' paper has the highest significance. "The popular idea that operating prolongs life even if imperfectly done is quite wrong. I believe this to be a perfect delusion. I believe that all these eleven patients would have lived longer if they had never been touched. Yet you hear the operation being constantly advised on the ground that if it does not cure it will at any rate give a little longer lease of life. On the contrary, the excitement and increased cell growth that are set up by an operation make everything that is left behind of a cancerous nature grow with double and treble speed, and I am inclined to think that the deaths after reappearance are more painful than where the cancer has not been touched. If a surgeon does not see his way to a clean sweep I can only implore him to let things alone, for in few diseases does meddlesome interference work more mischief than in this. It is but right that, whilst pleading the advantages of early and free operation, one should admit that, if it fails thoroughly to cure, it does not improve the patient's state, but makes it decidedly worse." It is true that these remarks are aimed at cases in which palpably cancerous tissue is left behind, but they apply also to operations which many surgeons still perform if the view taken by Mr Banks and others that "cancer germs" exist widely disseminated in the areolar tissue, the fat and lymphatic vessels round the focus of the disease be correct. The generality of surgeons, I believe, do not see their way to making quite such a clean sweep as Mr Banks advocates. They remove the whole breast as a rule, but this rule has its exceptions, especially when the growth is in the outer portion of the breast. Like the great John Hunter they remove all obviously affected glands, but they leave skin enough to cover the wound if the skin is to all appearance normal and is not adherent to the tumour. No palpably cancerous tissue is left behind, and a good margin of seemingly healthy tissue is taken away. Yet if the so-called "cancer germs" are more widely spread these operations must be regarded as incomplete and futile. Nevertheless some of these operations are attended with as good results as those which Mr Banks himself has obtained, whilst in others recurrence speedily takes place. How is this puzzling and seemingly anomalous circumstance to be explained? Recurrence of cancer of the breast after apparent excision of the entire disease and recurrence of the disease in the axilla several years after the operation is by modern theorists explained by the supposition that some germs of cancer have been left behind in the fat or perhaps in a portion of a lymphatic vessel or gland. Thus Mr Banks mentions the case of a woman over seventy years of age who was under his care and in whom a return of the disease occurred in the axilla four years and a half after complete removal of the breast and glands and a case of recurrence in another patient who had had the breast removed in America ten years previously. "During all that long period," says Mr Banks, "she remained apparently free, but some little fragment of gland tissue had been left in the upper and outer corner, there the disease once more sprang up and invaded the glands in a hopeless manner. One could not help deeply regretting that the surgeon had not made a

active, of doing too much rather than too little, whilst a do nothing and temporising policy was the special temptation of former times. Mr. Curling informed me that when he was assistant surgeon to the London Hospital he used constantly to supply his senior colleague with cases for operation and frequently suffered from the mortification of seeing such cases discharged from the wards without relief. Case after case even of necrosed bone—readily removable—met with this fate. The difficulty now is to restrain the surgeon from operating in unsuitable cases. When any new procedure is introduced it at once becomes necessary for every young surgeon to perform it as soon as possible if he is not to lag behind in the race for surgical honours. What a rush there was to do Ogston's operation for knock knee when it was first introduced. Every surgeon was envious of Ogston and was sorry that he had not thought of the procedure himself. Yet after a brief but not inglorious career, for there was much merit in the expedient, it was laid aside for the safer method of McEwen, and some, perhaps, who were loudest in its praise may have regretted that they ever performed it.

Another cause of the multiplication of surgical operations has been the increase in the number of surgical specialties. There is scarcely any organ in the body which is now left in the hands of the former tyrants of the medical world—the Fellows of the Royal College of Physicians of London—for almost every organ and every system of tissue in the human frame is cultivated by a surgical specialist. The office of every specialist must be magnified—his domain must be extended to its utmost limits. "Diseases of the throat," for instance, receive a generous interpretation from the laryngologist and from the suffering public and include all sorts and conditions of maladies affecting the miscellaneous structures between the base of the skull and the diaphragm. New diseases and new ramifications of old disease are discovered by the specialist and new instruments are invented for their removal. Some years ago Dr. Clifford Allbutt favoured the profession with a graphic description of the treatment which the long suffering uterus and especially the cervix uteri, had to endure, and a few weeks ago, in his Bradshaw Lecture, Mr. Christopher Heath was endeavouring to reduce the diseases of the nose to their lowest denomination. In the treatment of clubfoot there appears to be a danger that the safe and efficient operation of subcutaneous tenotomy which has conferred lustre on the name of Stromeyer, will be set aside for radical operations of doubtful value. Even the ear has not escaped the prevalent infection. Operations are now performed for the entire removal of an unperforated membrana tympani with the malleus, the incus and even the stapes.

The operative treatment of cancer, which has been extending itself in recent years, sometimes to the advantage and sometimes to the detriment of the individual patient, has been marvellously supported by the theory that cancer is only a local disease, at least in the first instance, as well as by the discovery of a "precancerous stage of cancer." No one can deny that there is and must be such a stage. The coming cancer does undoubtedly sometimes cast its shadow before, as exemplified in those cases of cancer of the breast which are preceded by eczema of the nipple as described by Sir James Paget.² The difficulty lies in recognising conditions which are really precancerous and in distinguishing them from like conditions which are absolutely innocent. In many cases this is practically impossible. Are we then to cut the Gordian knot and to doom to operation every removable part which exhibits a degeneration, a suspicious alteration or deviation from the normal which may have excited the fears of the patient? On such a principle every mole wart or excrescence, every scar, every imperfect or damaged organ—all of which are prone to become cancerous—ought to be removed without delay. Then there are the doubtful and puzzling cases in which it is extremely difficult to determine whether the disease is cancer or not, and certainly far more difficult to say whether it is likely to take on cancerous action at a future period. Two or three such cases, in which the breast was the seat of the affection, have come under my notice and in these I have usually advised delay. More than thirteen years ago a case of this kind came under my

care at the London Hospital. The patient has been under my observation ever since, and she is still alive and accessible. The particulars of the case, which was one of chronic induration of the breast with retracted nipple, I will now relate.—The wife of a labourer, forty six years of age, was admitted into the London Hospital under my care on July 19th, 1879, and was discharged on the 22nd. She was a healthy-looking woman, had borne seven children, six of whom are still living, and she had had three miscarriages. She always suckled her children for eight to ten months. At the time of her admission she had been married twenty-two years, and she had lived in the same locality all her life. The monthly period was just ceasing, and for the last twelve months her catamenia had been very irregular. She had been sent in for malignant disease of the right breast and as an urgent case for operation. Her medical advisers had told her that she would not live very long if she would not undergo an operation, and she had seen an eminent provincial surgeon who recommended her to have her breast removed on the ground that she was the subject of cancer. On examination the nipple of the right breast was seen to be retracted. The breast itself felt nodular, apparently from induration of the lobules, but on laying the hand flat on the organ and pressing it towards the chest no real tumour could be detected. The patient stated that the right nipple had always been small and that she seldom suckled with it. It had begun to recede two years previously, it was quite drawn in and could not be protruded. Both breasts were of fair size, well developed and of the same dimensions, and both were a little flaccid. Hard lobules could be felt in the left breast, but they were more pronounced in the right. Both breasts were very tender at each monthly period, and occasionally there was a thin watery discharge from the right nipple. The affection began with a pricking pain in the chest. Even now at times she has some uneasiness or pain either at the menstrual period or for two or three weeks, when it again disappears. The nipple always discharges a little. When she was in the hospital the case stood thus: no definite tumour in the breast, retraction of the nipple with watery discharge and hardness of the lobules, no perceptible glands in the axilla, skin over the breast healthy looking and freely movable, gland also movable and similar in appearance to its fellow save for the recession of the nipple, no family history of cancer, no wasting of any kind. From these features I diagnosed the case as one of chronic induration of the breast with retracted nipple and did not advise an operation. The patient herself had been much averse to being "cut about," as she expressed it, and received her reprieve with much satisfaction. Had the breast been amputated for cancer no doubt the case would have been quoted as an instance of cure by operation. Some may possibly think that it is safer to remove an organ of this kind, but I share the objection which the patient herself entertained to an avoidable mutilation.⁴

With regard to operations for genuine cancer, I always doubted whether, *taken as a whole* they succeeded in ensuring to patients operated on any real lengthening of life. General statistics, as distinguished from the complete statistics of individual surgeons, are most untrustworthy firstly, because they are largely compounded of the more or less favourable cases which have a tendency to be reported, whilst the cases which are fatal after operation or which the operation does not influence for good are allowed to pass without notice, and, secondly, because they include cases of very different kinds, some in which the disease was not cancer at all and others in different conditions and at different ages which are not comparable. Before statistics can be allowed to influence our decisions they ought to be thoroughly sifted and analysed so as to group together series of cases of a precisely similar kind both as regards age and exact variety and condition of the disease. If we look at cancer of the breast, for instance, how great is the difference in the course and duration of individual cases. Age, condition of the patient, and situation of the disease all have a modifying influence in regard to the rapidity of its development and the early or late termination of the case, and it is the same with cancer affecting other parts of the body. Undoubtedly there are cases of genuine scirrhus of the breast which have remained well after operation for a number of years—some, few as they may be, for eleven or twelve, some for seven or eight, some for three or four, but, on the other hand there are many

² Reference may be made to papers by Mr. Butlin in vols. ix and ix of the Medical and Chirurgical Transactions and to Mr. Bowley's paper in vol. lxxiv. Mr. Bowley gives thirteen cases. One is that of a lady aged sixty who had had the affection nearly five years. Mr. Thomas Smith amputated the breast. Its structure was in any except at the orifices of the ducts, and no growth was found in any part.

⁴ Mr. Jacobson advocates removal of the breast in such cases. See a note to a very able and interesting article on "The Precancerous Stage of Cancer of the Tongue" Guy's Hospital Report, 1890, p. 248.

which speedily recur, some which recur in an acute form owing to the operation itself, and others which if let alone run a chronic course, with little or no pain, and even without ulceration. The chance that the surgeon will lengthen the life of any individual patient by an operation appears to me not to be a very hopeful one. Sometimes it is not greater than the chance in a lottery in which there are a few prizes and many blanks. Apart, however, from lengthening the short span of human existence there are, of course, considerations which may entirely justify the surgeon in recommending an operation for cancer. The removal of an otherwise irremovable tumour whose presence may be a source of anxiety, worry or actual suffering, the likelihood, or at least the chance, that if the disease recurs its recurrent condition may be more endurable than its primary state—as Sir James Paget believes, though others think differently, the fact that sometimes, if not always, the general health of the patient, for a space at least, improves—are the surgeon's justification for recommending and sometimes even for pressing, an operation on a patient. In some situations—for example, in the mouth—the removal of the disease, it may be with a considerable portion of the jaw, is a great relief, and if the disease recurs it may recur in the glands only, and the surgeon has rendered the last days of the patient comparatively comfortable.

All the considerations here advanced as favourable to operations for cancer I admit to the full and as I have been in the habit of acting up to them in my own practice I can make a more forcible protest against the doctrine that all cases of cancer or suspected cancer wherein the disease can be removed are to be treated on the same lines and that operation is to be urged on everyone. We hear not very infrequently, of "cancers" which disappear or which turn out to be of an innocent nature, and others we meet with which would have lasted longer if let alone for an operation may light up the activity of a previously quiescent or very slowly advancing disease and thus may shorten the existence which it was intended to prolong. Some operations again, which are spoken of to the patient as being comparatively trivial and free from danger are very greatly the reverse. Excision of the mammary gland for cancer is generally represented to the patient as involving very little risk to life. Undoubtedly in the large majority of cases especially when the operation is performed upon the ancient lines admitting of conjunction of flaps the wound will quickly heal often by the first intention, and the recovery will be rapid and for the time complete, but the modern doctrine that "cancer germs" are distributed widely in the apparently sound superacut skin and in the axillary glands has led some to "return to the old plan of sweeping away everything and leaving a great hole at the primary seat of disease to fill up by granulations" as well as to supplement this with clearing out the axilla in a systematic manner. Whilst yet small, "the axillary glands and the whole fat and cellular tissue of the axilla can be pulled out with the fingers with the greatest ease." These are the words of Mr Mitchell Banks* who has been the most able prominent and successful advocate of the new method and he candidly admits that the operation performed in this thorough and sweeping way is "no longer a bit of surgical tailoring and that many more people will die from it" that "the opening of the axillary cavity adds not a little to the danger of the original operation," that "the wound is tremendous" that "the chasm left is something frightful to look at," and that "the whole procedure is accompanied with a very serious shock, seeing that thirty to forty minutes is the very shortest time in which it can be satisfactorily done." In three of his cases, "when the highest point of the axilla was reached it was found that there were still glands so adherent to the vein that they could not be removed whilst the condition of the patients was such that it was clear that the sooner they were off the table the better lest an immediate sinking should occur. The immediate mortality from this operation is calculated as amounting at present to 10 per cent., but Mr Banks reasonably believes that it is reducible to 5 6 or 7 per cent. as he has boldly dealt with cases which other surgeons would have been averse from touching, in order to give the patient a chance. In other cases he thinks he was scarcely bold enough. That he would have been justified in declining to operate on the less favourable ones is shown by his statistics. Out of forty six of his early cases six died after the operation and eleven had speedy

recurrence of the disease, nine of the eleven being dead and buried before the lapse of twelve months, one living fifteen months and the last a little longer. In several of these eleven cases it was impossible to remove all affected glands. Mr Banks has done good service in pointing out that no one can tell the state of the axillary glands till he sees them and that until the axilla is opened no one can be sure what he is going to find. Over and over again he has taken out of the armpit glands seriously affected when no glands could be felt even by the most careful handling by several persons. Often, too, they have extended high into the axilla and even into the neck when they were scarcely palpable externally and when exposed "some may shell out like peas and some may adhere to the vein like limpets to a rock." These statements I can myself confirm and they lend strong support to Mr Banks' contention that the axilla should always be explored in every case of removal of the breast for cancer, for, as Mr Banks observes, it is "worse than useless to make a great wound over the chest and leave affected glands in the axilla." With great ability Mr Banks contends that his method of making a clean sweep is the correct method of operating and as the generality of surgeons do not adopt it in its entirety the following extract from Mr Banks' paper has the highest significance. "The popular idea that operating prolongs life even if imperfectly done is quite wrong. I believe this to be a perfect delusion. I believe that all these eleven patients would have lived longer if they had never been touched. Yet you hear the operation being constantly advised on the ground that if it does not cure it will at any rate give a little longer lease of life. On the contrary, the excitement and increased cell growth that are set up by an operation make everything that is left behind of a cancerous nature grow with double and treble speed, and I am inclined to think that the deaths after reappearance are more painful than where the cancer has not been touched. If a surgeon does not see his way to a clean sweep I can only implore him to let things alone, for in few diseases does meddling interference work more mischief than in this. It is but right that, whilst pleading the advantages of early and free operation, one should admit that, if it fails thoroughly to cure, it does not improve the patient's state but makes it decidedly worse." These statements I can myself confirm and they lend strong support to Mr Banks' contention that the axilla should always be explored in every case of removal of the breast for cancer for, as Mr Banks observes, it is "worse than useless to make a great wound over the chest and leave affected glands in the axilla." With great ability Mr Banks contends that his method of making a clean sweep is the correct method of operating, and as the generality of surgeons do not adopt it in its entirety the following extract from Mr Banks' paper has the highest significance. "The popular idea that operating prolongs life even if imperfectly done is quite wrong. I believe this to be a perfect delusion. I believe that all these eleven patients would have lived longer if they had never been touched. Yet you hear the operation being constantly advised on the ground that if it does not cure it will at any rate give a little longer lease of life. On the contrary, the excitement and increased cell growth that are set up by an operation make everything that is left behind of a cancerous nature grow with double and treble speed, and I am inclined to think that the deaths after reappearance are more painful than where the cancer has not been touched. If a surgeon does not see his way to a clean sweep I can only implore him to let things alone for in few diseases does meddlesome interference work more mischief than in this. It is but right that, whilst pleading the advantages of early and free operation, one should admit that, if it fails thoroughly to cure, it does not improve the patient's state but makes it decidedly worse." It is true that these remarks are aimed at cases in which palpably cancerous tissue is left behind but they apply also to operations which many surgeons still perform if the view taken by Mr Banks and others that "cancer germs" exist widely disseminated in the areolar tissue the fat and lymphatic vessels round the focus of the disease be correct. The generality of surgeons I believe do not see their way to making quite such a clean sweep as Mr Banks advocates. They remove the whole breast as a rule, but this rule has its exceptions especially when the growth is in the outer portion of the breast. Like the great John Hunter they remove all obviously affected glands but they leave skin enough to cover the wound if the skin is to all appearance normal and is not adherent to the tumour. No palpably cancerous tissue is left behind, and a good margin of seemingly healthy tissue is taken away. Yet if the so-called "cancer germs" are more widely spread these operations must be regarded as incomplete and futile. Nevertheless some of these operations are attended with as good results as those which Mr Banks himself has obtained, whilst in others recurrence speedily takes place. How is this puzzling and seemingly anomalous circumstance to be explained? Recurrence of cancer of the breast after apparent excision of the entire disease and recurrence of the disease in the axilla several years after the operation is by modern theorists explained by the supposition that "some germs of cancer have been left behind in the fat or perhaps in a portion of a lymphatic vessel or gland. Thus Mr Banks mentions the case of a woman over seventy years of age who was under his care and in whom a return of the disease occurred in the axilla four years and a half after complete removal of the breast and glands and a case of recurrence in another patient who had had the breast removed in America ten years previously. During all that long period says Mr Banks 'she remained apparently free but some little fragment of gland tissue had been left in the upper and outer corner there the disease once more sprang up and invaded the glands in a hopeless manner. One could not help deeply regretting that the surgeon had not made a

⁶ Refer to my with advantage be made to two papers in the Pathological Society's Transactions for 1892, by Messrs. Raymond Johnson and Cecil F. Beadles p 170 and p 175.

clean sweep and carried away enough and more than enough when he was at it, as there could then have been no doubt about the cure being a permanent one." With these views of Mr Banks I cannot concur, for I do not believe that "cancer germs" would be so obliging as to remain quiescent and *perdus* in the axilla for ten years or even for four years and a half without making any sign. To my mind facts of this kind point to that constitutional element in cancer which it is the fashion of the pathology of the present day to ignore. The acceleration imparted to cancer by operation even after the cleanest sweep which has been compatible with the immediate preservation of life, the recurrence of cancer in an acute form in the whole lymphatic area of the original focus of the disease, and the constant return at the site of operation or in the neighbouring lymphatic glands are to myself the evidences of a constitutional cause. I will cite one or two examples of cases which tend to corroborate this view. In June, 1891, I was consulted by a lady sixty-three years of age who had a hard lump, I think, in the left breast, if I remember rightly. The tumour was a scirrhus cancer about the size of a Tangerine orange. The axillary glands were not palpably implicated, but as the patient was of a stout habit I could not feel certain on this point. She had first noticed the growth two or three years (I understood her myself to say three years) previously, and had suffered very little discomfort. The general health was good, and she did not appear to be nearly so anxious as her relatives. Having regard to her age and the other facts of the case, I gave it as my opinion that there was no necessity to be in a hurry to have the disease removed unless it was a source of mental distress and anxiety, but that I should like to see her again shortly before expressing a more decided opinion. The natural uneasiness of the patient's relatives led, as I anticipated and as usually happens in these cases, to a second opinion being taken, with the customary result that an immediate operation was advised. This advice was accepted. Excision was performed, but not, I believe, by the clean sweep advocated by Mr Banks. In a few months recurrence took place, and another surgeon removed the new growth or increased growth of old remaining germs, as the case may be. Again the disease recurred, and towards the end of last year I understand that another surgeon—the fourth in the sequence of consultants—operated on the patient, with what result I have not yet ascertained. Now no one can with certainty predict what course the disease would have taken if it had been let alone, my impression is that the patient would not have been worse off by the time that the third operation was performed. I have seen two cases of slightly ulcerated scirrhus cancer of the breast in patients over sixty which had lasted for several years, and I have seen the disease speedily return when excised. The second case is briefly this. In May, 1885, an unmarried lady forty-five years of age consulted me concerning a small hard tumour, of the size of a walnut, which occupied the right breast and had been noticed only ten days. The growth was freely movable, and there was no retraction of the nipple. There was no doubt as to the diagnosis, the patient elected to have the scirrhus tumour removed, and I performed the operation, taking away the whole of the gland. She remained well for nearly two years, when the left breast became the seat of scirrhus. Amputation of the gland was performed by another surgeon at a distance from London. For another year or more she continued well, and then the axillary glands on the left side, or the side on which the last operation had been performed, became involved. In January, 1889, the glands were removed by the surgeon who had excised the left breast, and by desire I was present and assisted at the operation. The disease proved to be rather more extensive than we had anticipated from external examination. Glands had to be dissected off the axillary vein, and one or two large tributaries joining the parent trunk had to be ligatured and removed. The operation was very skillfully performed, but the patient died on the second day, partly, I think, from shock and partly from commencing blood poisoning.

Now, recurrence of cancer on the side opposite to that from which it had been removed in the first instance can scarcely be due to any germs remaining behind after the primary operation and their transference to the other side of the body. The existence of a constitutional element seems to me the most reasonable explanation, and a further proof is the fact that cancerous patients may be benefited and the progress of the disease retarded by appropriate medical treatment. Iron and cod liver oil alteratives and remedies which act upon the liver may prove decidedly helpful to the patient.

Time will not permit of the discussion of this interesting
